Animal research has suggested that vitamin C may help prevent skin ulcers,<sup>7</sup> and in a preliminary study,<sup>8</sup> elderly patients with pressure ulcers had lower blood levels of vitamin C than did ulcer-free patients. Supplementation with vitamin C (3 grams per day) increased the speed of healing of leg ulcers in patients with a blood disorder called **thalassemia** (page 25), according to a double-blind study.<sup>9</sup> And while a double-blind trial of surgical patients with pressure ulcers found that supplementation with 500 mg of vitamin C twice a day accelerated ulcer healing,<sup>10</sup> a similar double-blind trial found no difference in the effectiveness of either 20 mg per day or 1,000 mg per day of vitamin C.<sup>11</sup>

An older preliminary report suggested that large amounts of **folic acid** (page 520) given both orally and by injection could promote healing of chronic skin ulcers due to poor circulation.<sup>12</sup> No controlled research has further investigated this claim.

**Zinc** (page 614) plays an important role in tissue growth processes important for skin ulcer healing. One study reported that patients with pressure ulcers had lower blood levels of zinc and iron than did patients without pressure ulcers,<sup>13</sup> and preliminary reports suggested zinc supplements could help some types of skin ulcer.<sup>14</sup> Supplementation with 150 mg of zinc per day improved healing in a preliminary study of elderly patients suffering from chronic leg ulcers.<sup>15</sup> Double-blind trials using 135 to 150 mg of zinc daily have shown improvement<sup>16</sup> only in patients with low blood zinc levels,<sup>17</sup> and no improvement in leg ulcer healing.<sup>18, 19</sup> A double-blind trial of 150 mg zinc per day in people with skin ulcers due to sickle cell anemia found that the healing rate was almost three times faster in the zinc group than in the placebo group after six months.<sup>20</sup> Lastly, a preliminary study of patients with skin ulcers due to leprosy found that 50 mg of zinc per day in addition to anti-leprosy medication resulted in complete healing in most patients within 6 to 12 weeks.<sup>21</sup> Long-term zinc supplementation at these levels should be ac-

companied by supplements of copper and perhaps calcium, iron, and magnesium. Large amounts of zinc (over 50 mg per day) should only be taken under the supervision of a doctor.

Topically applied zinc using zinc-containing bandages has improved healing of leg ulcers in double-blind studies of both zinc-deficient<sup>22</sup> and elderly individuals.<sup>23</sup> Most controlled comparison studies have reported that these bandages are no more effective than other bandages used in the conventional treatment of skin ulcers,<sup>24, 25</sup> but one controlled trial found non-elastic zinc bandages superior to alginate dressings or zinc-containing elastic stockinettes.<sup>26</sup> Two controlled trials of zinc-containing tape for foot ulcers due to leprosy concluded that zinc tape was similarly effective, but more convenient than conventional dressings.<sup>27, 28</sup>

Pressure ulcers and diabetic ulcers frequently develop in malnourished and/or institutionalized people. A double-blind study<sup>29</sup> of malnourished people compared topical application of 20 ml of a solution containing essential fatty acids (EFAs) and linoleic acid extracted from sunflower oil with a control solution containing topical mineral oil. Each solution was applied to the skin three times per day. Compared with the control solution, the solution containing EFAs significantly reduced the incidence of pressure ulcers and improved the hydration and elasticity of the skin.

A preliminary report suggested that **evening primrose oil** (page 511) improves blood flow to the legs and heals or reduces the size of venous leg ulcers.<sup>30</sup> No controlled research has further investigated this claim.

A double-blind trial found that a combination of 900 mg per day of diosmin and 100 mg per day of hesperidin, two members of the **flavonoid** (page 516) family, resulted in significantly greater healing of venous leg ulcers after two months.<sup>31, 32</sup> Related flavonoids known as hydroxyethylrutosides have also been investigated for venous ulcer healing. While one controlled study reported significant additional benefit when 2,000 mg per day of hydroxyethylrutosides were added to compression stocking therapy,<sup>33</sup> another double-blind trial using 1,000 mg per day found no effect on ulcer healing,<sup>34</sup> a second double-blind trial found no effect of 1,000 mg per day hydroxyethylrutosides on the prevention of venous ulcer recurrences.<sup>35</sup>

#### *Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

**Herbs that may be helpful**

**Gotu kola** (page 684) (*Centella asiatica*) extracts are sometimes used topically to help speed wound healing. Test tube studies have found that extracts of gotu kola high in the active triterpene constituents asiaticosides, madecassoides, asiatic acids, and madecassic acids increase collagen synthesis.<sup>36, 37</sup> An animal study found that topical application of asiaticoside isolated from gotu kola, used in a 0.2% solution, improved healing in nonulcer skin wounds.<sup>38</sup> An overview of three small human clinical trials suggests that topical use of an ointment or powder containing a gotu kola extract high in the active triterpene compounds may speed wound healing in people with slow-healing skin ulcers.<sup>39</sup> These studies used either a topical ointment with a 1% extract concentration or a powder with a 2% extract concentration. People in these studies were typically treated with intramuscular injections of either isolated asiaticosides or the mixed triterpenes three times per week while using the topical ointment or powder.

**Aloe vera** (page 624) has been used historically to improve wound healing and contains several constituents that may be important for this effect. A group of three patients who had chronic skin ulcerations for 5, 7, and 15 years, respectively, had a rapid reduction in ulcer size after the application of aloe gel on gauze bandages to the ulcers, according to a preliminary report.<sup>40</sup> A controlled study found most patients with pressure ulcers had complete healing after applying an aloe hydrogel dressing to the ulcers every day for ten weeks.<sup>41</sup> However, this result was not significantly better than that achieved with a moist saline gauze dressing. The amorphous hydrogel dressing used in the above study and derived from the aloe plant (Carrasyn Gel Wound Dressing, Carrington Laboratories, Irving, TX) is approved by the U.S. Food and Drug Administration for the management of mild to moderate skin ulcers.

**Are there any side effects or interactions?**

Refer to the individual herb for information about any side effects or interactions.

**Holistic approaches that may be helpful**

A double-blind trial found systemic hyperbaric oxygen (HBO) treatments, in which the patient is placed in a chamber with highly concentrated oxygen, five days per week for six weeks significantly improved healing of nondiabetic chronic leg ulcers.<sup>42</sup> This trial confirms the results from several preliminary studies of systemic

HBO therapy.<sup>43, 44</sup> While topical application of HBO (the affected body part is encased in a balloon-like chamber and exposed to concentrated oxygen) for skin ulcers has been reported effective in preliminary trials,<sup>45</sup> controlled trials have produced conflicting results.<sup>46, 47</sup> In controlled studies of diabetic patients with skin ulcers or gangrene, systemic HBO has been shown to prevent amputation of affected limbs.<sup>48, 49</sup>

Electrical stimulation applied to the skin is thought to have several biological effects that might accelerate skin ulcer healing.<sup>50</sup> A variety of techniques have been investigated, and controlled or double-blind trials have shown positive results for the use of low-voltage galvanic current, high-voltage pulsed current, transcutaneous electrical nerve stimulation (TENS), and pulsed high-frequency electromagnetic therapy.<sup>51</sup>

## SNORING

Snoring is caused by the movement of air across the soft tissues in the mouth or throat, such as the uvula, soft palate, and sometimes the vocal cords.

Any restriction of airflow, as occurs with nasal congestion, asthma, or polyps, increases the likelihood of snoring. Simple snoring is usually without health consequences, but inadequate sleep quality and quantity, nighttime dips in the body's oxygen levels,<sup>1</sup> and headaches<sup>2</sup> sometimes accompany snoring. In addition, an association between snoring and **heart disease** (page 98) has been established.<sup>3, 4</sup> When the resistance to airflow in the airways becomes so great as to cause significant interruptions in breathing, it is known as sleep apnea. Sleep apnea represents a more serious health concern than simple snoring;<sup>5</sup> therefore, chronic snoring, which can be associated with sleep apnea, should be evaluated by a healthcare provider.

**What are the symptoms of snoring?**

People with snoring may make a rough, rattling, noisy sound while breathing in during sleep.

**Medical treatments**

Healthcare practitioners may recommend avoidance of alcoholic beverages, sleeping pills, antihistamines, and overeating before bedtime. Sleeping on one side, rather than on the back, or raising the head of the bed may provide benefit. Weight loss is helpful, especially for

people who are obese. Allergies and nasal infections are treated when detected. Surgery may be recommended to correct structural problems with the airway, such as enlarged tonsils and adenoids or a deviated nasal septum.

### Lifestyle changes that may be helpful

Allergies can inflame the nasal passages, sinuses, and airways of the lungs, and commonly cause or contribute to snoring. Data collected from people with **allergic rhinitis** (page 407) (stuffy nose)<sup>6, 7</sup> and **asthma** (page 32)<sup>8, 9</sup> show that these people are more likely to be snorers than are nonallergic people. In addition, two preliminary studies have found that when snoring is treated using a continuous positive airway pressure device, an instrument primarily used to treat sleep apnea, nighttime asthma attacks decrease.<sup>10, 11</sup> Children who snore are also more likely than other children to have **allergies** (page 14),<sup>12</sup> and one preliminary study found that more than half of children with allergies are snorers.<sup>13</sup> One researcher reported that children with allergy symptoms, including snoring, commonly have **food sensitivities** (page 14). Although little more is known about food sensitivities and snoring, it may be helpful to test for food sensitivities.<sup>14</sup> The possibility of asthma and allergies should therefore be considered in people who snore.

A number of studies have found an association between snoring and heart disease. **High blood pressure** (page 246) and **coronary artery disease** (page 98) have been correlated with snoring in both men and women, and the correlation is stronger in people with normal weight.<sup>15, 16, 17, 18</sup> In women, snoring is more common after **menopause** (page 311), and is strongly associated with high blood pressure in women around the age of menopause.<sup>19, 20</sup> Researchers suggest that, with such a strong correlation, it is important to screen for hypertension and heart disease in people who snore.<sup>21</sup>

**Obesity** (page 446) and lack of physical activity are commonly associated with heavy snoring.<sup>22, 23</sup> Even in children, obesity may be linked to snoring and sleep disorders.<sup>24</sup> One study found that obese men who snore were significantly more likely to develop **diabetes** (page 152) over a ten-year period than were obese men who did not snore.<sup>25</sup> Snoring is clearly a problem that should be addressed in obese men, and increasing physical activity and weight loss are widely recommended.<sup>26, 27, 28</sup> A preliminary trial found that weight loss was more important in reducing snoring than either changes in sleep position or use of a nasal decongestant spray.<sup>29</sup> In a report by the U.S. Army, weight

control and physical training was advised to reduce the severity of snoring and sleep apnea, and in one presented case, full recovery from severe snoring was achieved with weight loss and use of a continuous positive airway pressure device.<sup>30</sup> Two other cases have been reported in which combined weight loss and use of a continuous positive airway pressure device resulted in full recovery from snoring and sleep apnea.<sup>31</sup>

Smoking increases the likelihood of snoring because of its effects on the nasal passages and sinuses.<sup>32</sup> In addition, nicotine may cause sleep disturbances that result in more snoring.<sup>33</sup> Men are more likely to snore as they age, but one study found that smoking increases the likelihood of snoring particularly in men under the age of 60.<sup>34</sup> A sleep study found that heavy smokers are more likely to snore than are moderate and light smokers, and that people who have quit smoking are no more likely to snore than are people who have never smoked.<sup>35</sup> Teenagers who smoke have also been found to be more likely to snore than non-smoking teenagers, and that snoring was associated with frequent nighttime wakening and daytime sleepiness.<sup>36</sup> Exposure to environmental smoke, or "second-hand smoke," has been shown to increase the likelihood of snoring in children.<sup>37, 38</sup> Smoking cessation and elimination of environmental smoke exposure are therefore important in the treatment of snoring.

It has long been thought that consumption of **alcohol** (page 12) contributes to snoring, and at least one study has found this to be true,<sup>39</sup> but several studies have been unable to verify this link.<sup>40, 41, 42</sup>

## SPRAINS AND STRAINS

### What do I need to know?

Self-care for sprains and strains can be approached in a number of ways—but it can be hard to know just where to start. To make it easier, our doctors recommend trying these simple steps first:

#### *Get professional help for serious injuries*

See a doctor if you cannot move or put weight on the body part, if the part looks crooked, if pain or tenderness is severe, if there is numbness or redness in the area, or if you have any other concerns about your injury.

#### *Control swelling and pain*

Use the R.I.C.E treatment: Rest the body part, Ice it every hour, Compress it with elastic band-

ages, tape, or a brace, and Elevate it above your heart

*Control inflammation with proteolytic enzymes*

Take 4 to 8 tablets a day of enzyme preparations containing trypsin, chymotrypsin, and/or bromelain for inflammation

*Try topical horse chestnut extract*

Apply a product containing 2% aescin every two hours to control swelling

*Take a multivitamin-mineral supplement*

A multivitamin during recovery can help insure against deficiencies that slow the healing process

### About sprains and strains

Sprains and strains are types of minor injuries to the soft tissues and connective tissues of the musculoskeletal system. Sprains usually refer to injuries to ligaments, but sometimes to other connective tissues, such as tendons and the capsules surrounding joints. Strains usually refer to injuries to muscles or to the areas where muscles become tendons.

Sprains and strains may occur together, and occasionally are quite severe, requiring immobilization of the body part in a rigid cast for weeks, long-term rehabilitation programs, and sometimes surgery.

### What are the symptoms of sprains and strains?

The most common type of sprain is the ankle sprain. Ankle sprains have differing degrees of severity. Mild or minimal sprains with no tear of the ligament usually produce mild tenderness and some swelling. Moderate sprains, in which the ligament has been partially ruptured, produce obvious swelling, **bruising** (page 84), significant tenderness, and difficulty walking. Severe sprains, as when the ligament is completely torn from the bone (called avulsion), make walking impossible and produce marked swelling, internal bleeding and joint instability.

Symptoms of strains include muscle soreness, muscle spasm, pain, and possibly swelling or warmth over the involved muscle.

### Medical treatments

Over the counter pain medications, such as aspirin (Bayer, Ecotrin, Bufferin), acetaminophen (Tylenol), and ibuprofen (Motrin, Advil), are routinely recommended to relieve minor pain and reduce inflammation. Topical methyl salicylate-menthol (Icy Hot,

Ben-Gay), trolamine salicylate (Aspercreme), and combination counterirritant products (Maximum Strength Flexall 454) may also help to relieve pain from muscle strain.

Prescription medications, such as acetaminophen with codeine (Tylenol with Codeine) or acetaminophen with hydrocodone (Vicodin), may be used for moderate pain. Strains may be treated with muscle relaxants, such as cyclobenzaprine (Flexeril), carisoprodol (Soma), and baclofen (Lioresal).

Treatment of minor sprains and strains includes resting the affected area, applying cold packs or ice, wrapping the area with a compression bandage (ACE), and keeping the affected area elevated as much as possible. Mild to moderate ankle sprains usually require strapping with elastic bandages or tape or immobilization with a brace. Health care providers recommend "RICE" for sprains and strains, which stands for rest, ice, compression, and elevation. A sprained ankle should always be X-rayed to rule out a fracture.

### CHECKLIST FOR SPRAINS AND STRAINS

Rating	Nutritional Supplements	Herbs
★★★	<b>Enzymes</b> (page 506) (chymotrypsin, trypsin)	
★★☆	<b>Bromelain</b> (page 481) <b>L-carnitine</b> (page 543) (for preventing exercise-related muscle injury) <b>Vitamin A</b> (page 595) (for deficiency only) <b>Vitamin C</b> (page 604) <b>Zinc</b> (page 614) (if deficient)	<b>Horse chestnut</b> (page 692) (topical)

### Dietary changes that may be helpful

Adequate amounts of calories and protein are required for the body to repair damaged connective tissue. While major injuries requiring hospitalization raise protein and calorie requirements significantly, minor sprains and strains do *not* require changes from a typical, healthful diet.<sup>1</sup>

### Nutritional supplements that may be helpful

**Proteolytic enzymes** (page 506), including bromelain, papain, trypsin, and chymotrypsin, may be helpful in healing minor injuries such as sprains and strains because they have anti-inflammatory activity and appear to promote tissue healing.<sup>2, 3, 4</sup>

Several preliminary trials have reported reduced pain and swelling, and/or faster healing in people with a variety of conditions using either bromelain,<sup>5</sup> papain from papaya,<sup>6, 7</sup> or a combination of trypsin and chymotrypsin.<sup>8</sup> Double-blind trials have reported faster recovery from athletic injuries, including sprains and strains, and earlier return to activity using eight tablets daily of trypsin/chymotrypsin,<sup>9, 10, 11, 12</sup> four to eight tablets daily of papain,<sup>13</sup> eight tablets of bromelain (single-blind only),<sup>14</sup> or a combination of these enzymes.<sup>15</sup> However, one double-blind trial using eight tablets per day of trypsin/chymotrypsin to treat sprained ankles found no significant effect on swelling, **bruising** (page 84), or overall function.<sup>16</sup>

**Bromelain** (page 481) is measured in MCUs (milk clotting units) or GDUs (gelatin dissolving units). One GDU equals 1.5 MCU. Strong products contain at least 2,000 MCU (1,333 GDU) per gram (1,000 mg). A supplement containing 500 mg labeled “2,000 MCU per gram” would have 1,000 MCU of activity, because 500 mg is half a gram. Some doctors recommend 3,000 MCU taken three times per day for several days, followed by 2,000 MCU three times per day. Some of the research, however, uses smaller amounts, such as 2,000 MCU taken in divided amounts in the course of a day (500 MCU taken four times per day). Other enzyme preparations, such as trypsin/chymotrypsin, have different measuring units. Recommended use is typically two tablets four times per day on an empty stomach, but as with bromelain, the strength of trypsin/chymotrypsin tablets can vary significantly from product to product.

One controlled trial showed that people who supplement with 3 grams per day **L-carnitine** (page 543) for three weeks before engaging in an exercise regimen are less likely to experience muscle soreness.<sup>17</sup>

**Antioxidant** (page 467) supplements, including **vitamin C** (page 604) and **vitamin E** (page 609), may help prevent exercise-related muscle injuries by neutralizing free radicals produced during strenuous activities.<sup>18</sup> Controlled research, some of it double-blind, has shown that 400–3,000 mg per day of vitamin C may reduce pain and speed up muscle strength recovery after intense exercise.<sup>19, 20</sup> Reductions in blood indicators of muscle damage and free radical activity have also been reported for supplementation with 400–1,200 IU per day of vitamin E in most studies,<sup>21, 22, 23</sup> but no measurable benefits in exercise recovery have been reported.<sup>24</sup> A combination of 90 mg per day of **coenzyme Q<sub>10</sub>** (page 496) and a very small amount of vitamin E did not produce any protective effects in one double-blind trial.<sup>25</sup>

**Vitamin C** (page 604) is needed to make collagen, the “glue” that strengthens connective tissue. Injury, at least when severe, appears to increase vitamin C requirements,<sup>26</sup> and vitamin C deficiency causes delayed healing from injury.<sup>27</sup> Preliminary human studies have suggested that vitamin C supplementation in non-deficient people can speed healing of various types of trauma, including musculoskeletal injuries,<sup>28, 29</sup> but double-blind research has not confirmed these effects for athletic injuries, which included sprains and strains.<sup>30</sup>

**Zinc** (page 614) is a component of many enzymes, including some that are needed to repair wounds. Even a mild deficiency of zinc can interfere with optimal recovery from everyday tissue damage as well as from more serious trauma.<sup>31</sup> Trace minerals, such as **manganese** (page 553), **copper** (page 499), and **silicon** (page 586) are also known to be important in the biochemistry of tissue healing.<sup>32, 33, 34, 35</sup> However, there have been no controlled studies of people with sprains or strains to explore the effect of deficiency of these minerals, or of oral supplementation, on the rate of healing.

Many vitamins and minerals have essential roles in tissue repair, and deficiencies of one or more of these nutrients have been demonstrated in animal studies to impair the healing process.<sup>36</sup> This could argue for the use of **multiple vitamin-mineral** (page 559) supplements by people with minor injuries who might have deficiencies due to poor diets or other problems, but controlled human research is lacking to support this.

**Glucosamine sulfate** (page 528) and **chondroitin sulfate** (page 492) may both play a role in **wound healing** (page 319) by providing the raw material needed by

the body to manufacture molecules called glycosaminoglycans found in skin, tendons, ligaments, and joints.<sup>37</sup> Test tube and animal studies have found that these substances, and others like them, can promote improved tissue healing.<sup>38, 39, 40, 41</sup> Injectable forms of chondroitin sulfate have been used in Europe for various types of sports-related injuries to tendons and joints,<sup>42, 43, 44, 45</sup> and one preliminary trial reported reduced pain and good healing in young athletes with chondromalacia patella (cartilage softening in the knee) who were given 750–1,500 mg per day of oral glucosamine sulfate.<sup>46</sup> However, specific human trials of glucosamine and chondroitin sulfate for healing sprains and strains are lacking.

The use of **DMSO** (page 508), a colorless, oily liquid primarily used as an industrial solvent, for therapeutic applications is controversial. However, some evidence indicates that dilutions, when applied directly to the skin, have anti-inflammatory properties and inhibit the transmission of pain messages by nerves, and in this way might ease the pain of minor injuries such as sprains and strains.<sup>47, 48, 49</sup> However no controlled research exists to confirm these effects in sprains and strains. DMSO comes in different strengths and different degrees of purity. In addition, certain precautions must be taken when applying DMSO. For those reasons, DMSO should be used only with the supervision of a doctor.

#### *Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

#### **Herbs that may be helpful**

**Horse chestnut** (page 692) contains a compound called aescin that acts as an anti-inflammatory and reduces **edema** (page 177) (swelling with fluid) following trauma, particularly sports injuries, surgery, and head injury.<sup>50</sup> A topical gel containing 2% of the compound aescin found in horse chestnut is widely used in Germany to treat minor sports injuries, including sprains and strains.<sup>51</sup> The gel is typically applied to affected area every two hours until swelling begins to subside.

Arnica is considered by some practitioners to be among the most effective **wound-healing** (page 319) herbs available.<sup>52</sup> As a homeopathic remedy, arnica is often recommended as both an internal and topical mean to treat minor injuries. Some healthcare practitioners recommend mixing 1 tablespoon of arnica tinc-

ture in 500 ml water, then soaking thin cloth or gauze in the liquid and applying it to the injured area for at least 15 minutes four to five times per day.

**Comfrey** (page 662) is also widely used in traditional medicine as a topical application to help heal wounds.<sup>53</sup>

#### *Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

#### **Holistic approaches that may be helpful**

Spinal manipulation is used by chiropractors, licensed naturopathic doctors, and some osteopathic doctors to relieve pain and improve healing of sprains and strains. One preliminary trial tested a combination of chiropractic manipulation, muscle stretching, and special exercises known as “proprioceptive neurofacilitation” to people who had sprain/strain neck injuries that had not resolved with other treatment.<sup>54</sup> Treatment was reported to help the majority of people, and over one-third reported that their symptoms were completely gone or only mildly bothersome. In a larger preliminary trial,<sup>55</sup> people who were still suffering neck pain a year after whiplash-type accidents were treated with spinal manipulation for an average of four months. At the end of the treatments, 72% reported at least some benefit and nearly half reported significant benefit or complete recovery, but people with the most severe symptoms derived little benefit.

## STRESS

#### **About stress**

The popular idea of stress in relation to human health is often described as an unpleasant mental or emotional experience, as when people say they are “stressed out.” This expression relates primarily to the idea of prolonged or sudden and intense stress, which can have unpleasant effects on the body, impairing the ability to function, and even harming health.<sup>1, 2, 3</sup> However, the biological concept of stress is much more broadly defined as any challenge (physical or psychological) that requires an organism to adapt in a healthy manner. In other words, responses to stress can sometimes be of benefit when the organism is strengthened by the experience. The discussion below focuses on reducing the effects of excessive, unwanted stress.

CHECKLIST FOR STRESS		
Rating	Nutritional Supplements	Herbs
★★★	Tyrosine (page 465) Vitamin C (page 604)	Rhodiola (page 738)
★★☆	DHA (page 509) (docosahexaenoic acid) Flaxseed (page 517) Multivitamin-mineral supplement (page 559)	Asian ginseng (page 630) Eleuthero (page 672)
★☆☆	Probiotics (page 575)	Ashwagandha (page 629)

### What are the symptoms of stress?

Symptoms may include anxiety, fatigue, **insomnia** (page 270), stomach problems, sweating, racing heart, rapid breathing, shortness of breath, and irritability. Many health problems have been associated with various kinds of sudden or long-term stress, including **alcohol abuse** (page 12),<sup>4</sup> **asthma** (page 32),<sup>5</sup> **chronic fatigue** (page 111),<sup>6,7</sup> **erectile dysfunction** (page 185) and **male infertility** (page 305),<sup>8</sup> **fibromyalgia** (page 191),<sup>9</sup> headaches,<sup>10</sup> heart disease,<sup>11, 12, 13</sup> **high blood pressure** (page 246),<sup>14, 15</sup> **immune system** (page 255) dysfunction,<sup>16, 17, 18</sup> **indigestion** (page 260), **irritable bowel syndrome** (page 280),<sup>19</sup> mood disorders such as **anxiety** (page 30) and **depression** (page 145),<sup>20, 21</sup> **peptic ulcers** (page 349),<sup>22</sup> **pregnancy** (page 363) complications,<sup>23, 24, 25</sup> **rheumatoid arthritis** (page 387),<sup>26</sup> skin diseases,<sup>27</sup> impaired **wound healing** (page 357),<sup>28</sup> and others.<sup>29, 30, 31, 32, 33, 34</sup> Problems with recovery from surgery and impaired workplace performance are also associated with excessive stress.<sup>35, 36, 37, 38</sup>

### Medical treatments

Over-the-counter treatment is limited, but sleep aids containing diphenhydramine (Benadryl, Sominex, Nyquil) and doxylamine (Unisom) might relieve stress-induced **insomnia** (page 270).

Prescription medications used to treat anxiety, a condition related to stress, include the benzodiazepines lorazepam (Ativan), alprazolam (Xanax), clonazepam (Klonopin), and diazepam (Valium), as well as buspirone (Buspar) and hydroxyzine pamoate (Vistaril). Other benzodiazepines, such as estazolam (ProSom) and flurazepam (Dalmane), as well as zolpidem (Ambien) might provide short term relief for stress-related insomnia. People with panic attacks and depression might benefit from the selective serotonin reuptake in-

hibitors paroxetine (Paxil), sertraline (Zoloft), and fluoxetine (Prozac).

Medical management of stress includes teaching people how to avoid or cope with stressful situations and encouraging a healthful diet, good exercise habits, and adequate sleep. Those unable to find relief on their own might benefit from professional counseling.

### Dietary changes that may be helpful

**Flaxseed** (page 517) is a good source of **fiber** (page 512) and alpha-linolenic acid (an **omega-3 fatty acid** [page 509]) and is a major source of lignans that may influence hormone function. A controlled study found that adding 30 grams per day of freshly ground flaxseed to the diets of **postmenopausal women** (page 311) reduced the blood pressure-elevating effect of mental stress and reduced stress-related changes in fibrinogen, a blood component associated with increased risk of heart disease.<sup>39</sup> However, flaxseed had no significant effect on blood levels of an adrenal stress hormone.

### Lifestyle changes that may be helpful

While cigarette smokers often describe their habit as relaxing, smoking is associated with increased stress levels,<sup>40</sup> and stopping the habit eventually results in reduced feelings of stress.<sup>41</sup>

Drinking alcohol can reduce feelings of stress,<sup>42</sup> but using **alcohol** (page 12) regularly in response to chronic or repetitive stress can lead to an unhealthy dependency.

Exercise has long been thought to have potential benefits to mental health and stress reduction;<sup>43, 44</sup> however, exercise can also be stressful when it is intense or competitive.<sup>45, 46</sup> Many preliminary studies have found that regular exercisers score higher on measures of psychological well-being and perceived stress,<sup>47, 48, 49, 50, 51</sup> and that people who improve their exercise habits develop changes in their mental attitudes that are associated with better resistance to stress.<sup>52</sup> A controlled trial found that a single session of aerobic exercise reduced the anxiety associated with a subsequent experience designed to be psychologically stressful.<sup>53</sup> However, studies of overall aerobic fitness have found that people with higher fitness levels are not different from those with lower fitness in their resistance to stress. One preliminary study gave aerobically fit and unfit women a mentally stressful test, and found no differences between them in physical or psychological measures of their stress reaction.<sup>54</sup> Another preliminary study found that while physical activity was associated with reduced

stress symptoms, having high aerobic fitness had no influence.<sup>55</sup> This may mean that effects other than improved aerobic fitness, such as an improved self-image or the social support from belonging to an exercise group, are responsible for the benefits of exercise on controlling stress. A preliminary study in Thailand found that postmenopausal women who completed an aerobic exercise program consisting of 40- to 50-minute sessions twice weekly for 12 weeks had improved scores on a questionnaire designed to measure psychological stress.<sup>56</sup> In a controlled trial, cancer patients hospitalized for chemotherapy who exercised for 30 minutes daily until discharge had significant improvement in several measures of psychological distress, while a similar group who did not exercise showed no change in these measures.<sup>57</sup> In a controlled trial, 10 weeks of aerobic exercise resulted in healthier responses to acute mental stress in college students compared with students who did no exercise.<sup>58</sup>

#### Nutritional supplements that may be helpful

**Tyrosine** (page 465) is an **amino acid** (page 465) used by the body to produce certain adrenal stress hormones and chemical messengers in the nervous system (neurotransmitters). Animal research shows that brain levels of these substances decline with stress, and that giving animals tyrosine supplements reverses this decline and improves various tests of performance in stressed animals.<sup>59</sup> In a controlled study, a protein drink containing 10 grams per day of tyrosine was more effective than a carbohydrate drink for improving mental performance scores in a group of cadets taking a stressful six-day combat training course.<sup>60</sup> A double-blind trial in humans found that one-time administration of 150 mg of tyrosine per 2.2 pounds of body weight helped prevent a decline in mental performance for about three hours during a night of sleep deprivation.<sup>61</sup> Single administrations of tyrosine (100 to 150 mg per 2.2 pounds of body weight) have also helped preserve mental performance during physically stressful conditions such as noise or extreme cold in several controlled studies.<sup>62, 63, 64, 65</sup>

Animal studies suggest that supplementing with **vitamin C** (page 604) can reduce blood levels of stress-related hormones and other measures of stress.<sup>66, 67, 68, 69</sup> Controlled studies of athletes have shown that vitamin C supplementation (1,000 to 1,500 mg per day) can reduce stress hormone levels after intense exercise.<sup>70, 71</sup> Surgery patients given 2,000 mg per day of vitamin C during the week before and after surgery had a more

rapid return to normal of several stress-related hormones compared with patients not given vitamin C.<sup>72</sup> In a double-blind trial, young adults took 3,000 mg per day of vitamin C for two weeks, then were given a psychological stress test involving public speaking and mental arithmetic.<sup>73</sup> Compared with a placebo group, those taking vitamin C rated themselves less stressed, scored better on an **anxiety** (page 30) questionnaire, had smaller elevations of blood pressure, and returned sooner to lower levels of an adrenal stress hormone following the stress test.

Animal and human studies suggest that deficiencies of **omega-3 fatty acids** (page 509) may contribute to behaviors associated with unhealthy responses to stress.<sup>74, 75</sup> A double-blind study of students with a low dietary intake of **DHA** (page 509) (docosahexaenoic acid, an omega-3 fatty acid) reported that taking 1.5 to 1.8 grams of DHA per day for three months prevented an increase in aggressiveness in these students during a stressful final exam period.<sup>76</sup> This group of researchers reported in another double-blind study that 1.5 grams per day of DHA given to medical students during a stressful exam period resulted in changes in some, though not all, blood measurements indicating improved responses to stress.<sup>77</sup>

When asked why they are taking nutritional supplements, combating stress is one of the most common reasons given by people.<sup>78, 79, 80</sup> Despite this popular attitude, human research on the effects of supplements on stress is sparse and conflicting.<sup>81</sup> While there are animal studies and preliminary human reports suggesting that many vitamins are important for protecting the body from the consequences of physical stresses such as surgery,<sup>82</sup> evidence supporting the use of vitamins to combat everyday stress is somewhat limited.

Several studies have evaluated a daily supplement of **vitamin B<sub>1</sub>** (page 597) (15 mg), **vitamin B<sub>2</sub>** (page 598) (15 mg), **vitamin B<sub>3</sub>** (page 598) (50 mg), **vitamin B<sub>6</sub>** (page 600) (10 mg), **vitamin B<sub>12</sub>** (page 601) (10 mcg), **vitamin C** (page 604) (500 mg), pantothenic acid (23 mg), **folic acid** (page 520) (400 mcg), **biotin** (page 473) (150 mcg), **calcium** (page 483) (100 mg), **magnesium** (page 551) (100 mg), and **zinc** (page 614) (10 mg) for combating stress effects. People participating in preliminary trials of this combination have reported some benefits that relate to the effects of chronic stress, including improved concentration, better mood, and less fatigue.<sup>83, 84</sup> A small double-blind study of this combination reported no significant psychological benefits relating to stress.<sup>85</sup> However, in a larger double-

blind trial with healthy young men, this supplement resulted in significantly less anxiety and perceived stress according to some measurements after one month, though other stress-related symptoms did not improve.<sup>86</sup> Another large, double-blind study of people experiencing high stress levels found this combination significantly helpful after one month according to several measures of anxiety, well-being, and psychological stress.<sup>87</sup>

In a year-long double-blind trial, a one-a-day type **multivitamin-mineral supplement** (page 559) was no better than a supplement containing only **vitamin B<sub>2</sub>** (page 598), **calcium** (page 483), and **magnesium** (page 551) for improving mental or physical measures of quality of life in a group of healthy adults.<sup>88</sup>

Stress is understood to have a detrimental effect on the balance of intestinal bacteria,<sup>89, 90</sup> but whether **probiotic** (page 575) supplements improve the ability to handle stress is unknown. In a six-month preliminary trial, a **multivitamin-mineral (MVM) supplement** (page 559) that also contained a blend of *Lactobacillus acidophilus*, *Bifidobacterium bifidum*, and *Bifidobacterium longum* was effective for improving scores on a stress questionnaire.<sup>91</sup> However, this improvement could have been a placebo effect or could have been due to the MVM component. Controlled research comparing MVM supplements with and without added probiotics is necessary to determine whether probiotics are helpful for treating stress.

#### *Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

#### **Herbs that may be helpful**

The herbs discussed here are considered members of a controversial category known as adaptogens, which are thought to increase the body's resistance to stress, and to generally enhance physical and mental functioning.<sup>92, 93</sup> Many animal studies have shown that various herbal adaptogens have protective effects against physically stressful experiences,<sup>94, 95</sup> but whether these findings are relevant to human stress experiences is debatable.

Animal studies have demonstrated protective effects of **rhodiola** (page 738) extracts against physical stresses.<sup>96, 97, 98</sup> A double-blind study of healthcare workers experiencing the stress of night duty found that taking 170 mg per day of a standardized rhodiola extract prevented some of the decline in a set of mental

performance measures during the first two weeks. However, when this regimen was repeated after a two-week period of not taking the extract, rhodiola did not provide protection from mental performance decline.<sup>99</sup> In another double-blind study, 100 mg per day of the same extract was given to medical students during a stressful exam period. Those taking the extract reported a better sense of general well-being, and performed better on tests of mental and psychomotor performance.<sup>100</sup> A third double-blind study of military cadets performing a 24-hour duty showed that 370 to 555 mg of rhodiola extract per day significantly reduced mental fatigue, as measured by several performance tasks.<sup>101</sup>

Animal studies support the idea that **Asian ginseng** (page 630) is an adaptogen.<sup>102</sup> Some studies have suggested that Asian ginseng can enhance feelings of well-being in elderly people with **age-associated memory impairment** (page 8),<sup>103</sup> nurses working night shifts,<sup>104</sup> or people with **diabetes** (page 152).<sup>105</sup> In a double-blind trial, people taking a daily combination of a **multivitamin-mineral supplement** (page 559) (MVM) with 40 mg of ginseng extract (standardized for 4% ginsenosides) for 12 weeks reported greater improvements in quality of life measured with a questionnaire compared with a group taking only MVM.<sup>106</sup> The same MVM-ginseng combination was tested in a double-blind study of night-shift healthcare workers.<sup>107</sup> Compared with a placebo group, the group receiving the MVM-ginseng combination improved on one out of four measures of mental performance, one out of three measures of mood (increased calmness, but no change in alertness or contentment), and a measure of reported fatigue. However, in another double-blind study, healthy adults given 200 or 400 mg per day of a standardized extract of Asian ginseng (equivalent to 1,000 or 2,000 mg of ginseng root) showed no significant improvement in any of several measures of psychological well-being after two months.<sup>108</sup>

Animal research has reported antistress effects of **Eleutherococcus senticosus** (page 672) (also known as Siberian ginseng),<sup>109</sup> and Russian research not available in the English language reportedly describes human studies showing similar effects in humans.<sup>110, 111</sup> A double-blind study of healthy elderly people reported that those who took 60 drops per day of a eleuthero liquid extract (concentration not specified) scored higher in some quality-of-life measures after four weeks, but not after eight weeks, compared with a group taking a placebo.<sup>112</sup> Athletes experiencing the stress of training who took an eleuthero extract equivalent to 4 grams per

day had no changes in their blood levels of an adrenal stress hormone after six weeks.<sup>113</sup> More research is needed to clarify the value of eleuthero for treating stress.

Animal studies have suggested that **ashwagandha** (page 629) may be helpful for reducing the effects of stress,<sup>114, 115, 116</sup> including chronic psychological stress.<sup>117</sup> However, no controlled research has been done to explore these effects in humans.

An herbal formula from the Ayurvedic medicine tradition, containing extracts of **ashwagandha** (page 629), asparagus, pueraria, argyreia, dioscorea, mucuna, and piper, has been studied as an aid to coping with the stress of military combat. A double-blind study found that soldiers performed similarly in a set of mental and psychological tests after an eight-day combat mission whether they were given two capsules daily (exact content not revealed) of this formula or a placebo.<sup>118</sup> This suggests there was no real benefit of the herbal formula under these conditions.

#### *Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

#### **Holistic approaches that may be helpful**

Mind-body medicine is a branch of healing that focuses on the role of thoughts and emotions on physical health. Many techniques used in this healing system, including biofeedback, relaxation training, tai chi, yoga, and meditation, affect the nervous system in ways that could theoretically help people cope with stress.<sup>119</sup> In a controlled trial, tai chi practice, meditation, walking exercise, and quiet reading all resulted in similar biochemical and psychological improvements in the response to a stressful experience.<sup>120</sup> Meditation, practiced for spiritual reasons, for relaxation, or as part of the treatment of a disease, has been reported helpful for stress reduction in preliminary studies.<sup>121, 122, 123</sup> A controlled study found 15 minutes of meditation twice a day reduced measures of stress in adolescents during two experiences designed to produce stress.<sup>124</sup> Other controlled studies have found reductions in reported stress and related psychological measures after a program of meditation.<sup>125, 126</sup>

Stress reduction programs involving combinations of group counseling, instruction in coping skills and problem-solving, relaxation training, meditation, or other methods are effective for reducing stress and helping to prevent or manage health problems relating

to stress, according to preliminary and controlled research.<sup>127, 128, 129, 130, 131, 132</sup>

## STROKE

Stroke is a condition caused by a lack of blood supply to the brain or by hemorrhage (bleeding) within the brain.

Stroke is the third leading cause of death in the United States, but most strokes are not fatal. Depending on the area of the brain that is damaged, a stroke can cause coma, reversible or irreversible paralysis, speech problems, visual disturbances, and dementia. Factors that increase the risk of certain types of stroke include **hypertension** (page 246), **diabetes** (page 152), elevated levels of **high cholesterol** (page 223) or **homocysteine** (page 234), and **atherosclerosis** (page 38) (hardening of the arteries) of the blood vessels that supply the brain.

#### CHECKLIST FOR STROKE

Rating	Nutritional Supplements	Herbs
★☆☆	<b>Potassium</b> (page 572) <b>Vinpocetine</b> (page 594)	
★☆☆	<b>Folic acid</b> (page 520) (for high homocysteine only) <b>Magnesium</b> (page 551) <b>Tocotrienols</b> (page 593) <b>Vitamin B<sub>6</sub></b> (page 600) (for high homocysteine only) <b>Vitamin B<sub>12</sub></b> (page 601) (for high homocysteine only) <b>Vitamin E</b> (page 609)	

#### **What are the symptoms of stroke?**

Symptoms of stroke include weakness, numbness, or inability to move an arm or leg; sudden and intense headache; severe dizziness or loss of coordination and balance; difficulty with speaking or understanding; and blurred or decreased vision in one or both eyes. People with stroke may also have seizures, vomiting, drooling, and difficulty swallowing. Some people experience temporary warning episodes of neurologic symptoms called transient ischemic attacks (TIAs) before suffering a complete stroke. People experiencing symptoms suggestive of having suffered a stroke or a TIA require immediate (emergency room) medical attention.

### Medical treatments

Over the counter aspirin (Bayer Low Adult Strength, Ecotrin Adult Low Strength) may help prevent future strokes in men.

Prescription anticoagulants, such as warfarin (Coumadin) are routinely given to individuals who have had strokes.

Individuals who experience a stroke caused by blockage of blood vessels (ischemic stroke) receive clot-dissolving (thrombolytic) medications, such as recombinant tissue plasminogen activator (Alteplase) and the anticoagulant heparin. Individuals who have a stroke due to bleeding in the brain (hemorrhagic stroke) usually receive a surgical procedure that stops bleeding and repairs blood vessels. After the acute treatment of stroke, doctors often recommend rehabilitation, including physical, speech, and occupational therapy.

### Dietary changes that may be helpful

Researchers have found an association between diets low in **potassium** (page 572) and increased risk of stroke.<sup>1, 2, 3</sup> People who take potassium supplements have been reported to have a low risk of suffering a stroke.<sup>4</sup> However, the association of increasing dietary potassium intake and decreasing stroke mortality only occurred in black men and **hypertensive** (page 246) men in one study.<sup>5</sup> Others have found an association between increased risk of stroke and the combination of low dietary potassium plus high salt intake.<sup>6</sup> Increasing dietary potassium has lowered blood pressure in humans, which by itself should reduce the risk of stroke.<sup>7</sup> However, some of the protective effect of potassium appears to extend beyond its ability to **lower blood pressure** (page 246).<sup>8</sup> Maintaining a high potassium intake is best achieved by eating fruits and vegetables.

Diets high in fruit and/or vegetables are associated with a reduced risk of stroke, according to most studies.<sup>9, 10</sup> In a large preliminary study, cruciferous and green leafy vegetables, as well as citrus fruit and juice, conferred the highest degree of protection.<sup>11</sup> Because it is not clear which components of fruits and vegetables are most responsible for the protective effect against stroke, people wishing to reduce their risk of stroke should rely primarily on eating more fruits and vegetables themselves, rather than taking supplements.

A large study also found that women who eat higher amounts of whole grains are at lower risk of ischemic stroke.<sup>12</sup> Those women who ate more than one whole-grain food on an average day (twice the amount of **fiber** (page 512) eaten by the average American) had approx-

imately a 35% lower risk of suffering an ischemic stroke compared with women who ate virtually no whole-grain products on an average day. This study fits with previous research showing that women who consume more whole grains are also at reduced risk for **heart disease** (page 98) caused by **atherosclerosis** (page 38).

The influence of dietary fat on the risk of stroke is not as clear as it is for heart disease risk. Some recent reports suggest an association between increased fat intake, including saturated fat (primarily found in meat and dairy), and a *decreased* stroke risk.<sup>13, 14</sup> These unexpected findings may be due to unique dietary conditions in the country studied (Japan) or to flaws in study design.<sup>15, 16, 17</sup> Other evidence suggests the opposite relationship—that people consuming more saturated fat are at *higher* risk of stroke.<sup>18</sup>

Evidence regarding the role of unsaturated fats (primarily found in vegetable oils, cooked and processed foods made with vegetable oils, nuts, and seeds) is equally unclear,<sup>19, 20, 21</sup> suggesting that unsaturated fats may have varying effects on different types of stroke or that some unsaturated fats differ from others in their influence on stroke risk.

Evidence is accumulating in favor of fish consumption, a rich source of **omega-3 fatty acids** (page 509), as a way to help prevent stroke. Eating fish has been linked to reduced stroke risk in most,<sup>22, 23, 24</sup> but not all,<sup>25, 26</sup> studies.

High salt intake is associated with both stroke<sup>27</sup> and **hypertension** (page 246), a major risk factor for stroke.<sup>28</sup> Salt intake may increase stroke risk independent of its effect on blood pressure.<sup>29</sup> Among **overweight** (page 446) people, an increase in salt consumption of about 1/2 teaspoon (2.3 grams) per day was associated with a 32% increase in stroke incidence and an 89% increase in stroke mortality.<sup>30</sup> Reducing salt intake is recommended as a way to reduce the risk of stroke.<sup>31</sup>

Having one or two drinks per day has lowered stroke risk in most studies,<sup>32, 33</sup> though some researchers report no protection<sup>34</sup> and others find that even light drinking leads to an increased risk of stroke.<sup>35</sup> Regular heavy drinking or binge drinking, however, has consistently raised the risk of suffering a stroke by increasing **blood pressure** (page 246) and causing heart muscle abnormalities and other effects.<sup>36, 37, 38</sup>

### Lifestyle changes that may be helpful

Smoking is associated with a significantly increased risk of stroke.<sup>39, 40, 41</sup> Even secondhand smoke puts non-smokers at increased risk.<sup>42</sup>

Exercise reduces the risk of stroke according to most,<sup>43, 44, 45, 46</sup> though not all,<sup>47</sup> studies. The benefits of exercise are probably due to its effects on body weight, **blood pressure** (page 246), and glucose tolerance.

**Obesity** (page 446) has been associated with an increased risk of stroke in most studies.<sup>48, 49</sup> Excess abdominal fat appears to be more directly linked to increased risk of stroke, compared with fat accumulation in the thighs and buttocks.<sup>50, 51, 52</sup> While losing weight and keeping it off is difficult for most people, normalizing weight with a healthful diet and exercise program is one of the best ways to reduce the risk of many diseases, including stroke.

### Nutritional supplements that may be helpful

**Vinpocetine** (page 594) given by intravenous injection has been reported to improve some biochemical measures of brain function in stroke patients.<sup>53, 54</sup> A controlled trial found intravenous vinpocetine given within 72 hours of a stroke reduced some of the losses in brain function that typically follow a stroke.<sup>55</sup> However, the reliability of human stroke research using vinpocetine has been questioned,<sup>56, 57</sup> and more double-blind trials are needed. No studies using oral vinpocetine for treating acute strokes have been published.

Elevated blood levels of **homocysteine** (page 234), a toxic **amino acid** (page 645) byproduct, have been linked to risk of stroke in most studies.<sup>58, 59, 60</sup> What is not clear, however, is whether high homocysteine levels cause strokes or are simply a marker for some other causative factor. Supplementation with **folic acid** (page 520), **vitamin B<sub>6</sub>** (page 600), and **vitamin B<sub>12</sub>** (page 601) generally lowers homocysteine levels in humans.<sup>61, 62, 63</sup> Whether lowering homocysteine will result in a decrease in the risk of suffering a stroke, however, remains unknown.

Narrowing of the neck arteries (carotid stenosis) caused by **atherosclerosis** (page 38) is a risk factor for stroke. Preliminary diet studies have found that people who eat foods high in **antioxidants** (page 467) such as **vitamin C** (page 604) and **vitamin E** (page 609) have less carotid stenosis.<sup>64, 65</sup>

In a double-blind trial, people with atherosclerosis in the carotid arteries were given a palm oil extract containing 160–240 mg of **tocotrienols** (page 593) (a vitamin E-like supplement) and approximately 100–150 IU **vitamin E** (page 609) per day. After 18 months, they had significantly less atherosclerosis or less progression of atherosclerosis compared to a group receiving placebo.<sup>66</sup> Vitamin E plus aspirin, has been more

effective in reducing the risk of strokes and other related events than has aspirin, alone.<sup>67</sup> However, most preliminary trials have shown no protective effects from antioxidant supplementation.<sup>68, 69, 70, 71, 72, 73</sup> A large Finnish trial concluded that supplementation with either vitamin E or **beta-carotene** (page 469) conferred no protection against stroke in male smokers,<sup>74</sup> although a later review of the study found that those smokers who have either **hypertension** (page 246) (high blood pressure) or **diabetes** (page 152) do appear to have a reduced risk of stroke when taking vitamin E.<sup>75</sup>

People with high risk for stroke, such as those who have had TIAs or who have a heart condition known as atrial fibrillation,<sup>76</sup> are often given aspirin or anticoagulant medication to reduce blood clotting tendencies. Some natural inhibitors of blood clotting such as **garlic** (page 679, 78, 79) **fish oil** (page 514),<sup>80</sup> and **vitamin E** (page 609),<sup>81, 82</sup> may have protective effects, but even large amounts of fish oil are known to be less potent than aspirin.<sup>83</sup> Whether any of these substances is an adequate substitute to control risk of stroke in high-risk people is unknown, and anyone taking anticoagulant medication should advise their prescribing doctor before beginning use of these natural substances.

Researchers have found an association between diets low in **magnesium** (page 551) and increased risk of stroke, an effect explained partially, but not completely, by the ability of magnesium to reduce **high blood pressure** (page 246).<sup>84</sup> Protection from stroke associated with drinking water high in magnesium has also been reported.<sup>85</sup> Intravenous magnesium given immediately after a stroke has been proposed as a treatment for reducing stroke deaths,<sup>86</sup> but results so far have been inconclusive.<sup>87</sup>

### Are there any side effects or interactions?

Refer to the individual supplement for information about any side effects or interactions.

## SYSTEMIC LUPUS ERYTHEMATOSUS

Systemic lupus erythematosus (SLE) is an autoimmune illness that causes a characteristic butterfly-shaped rash on the face accompanied by inflammation of connective tissue, particularly joints, throughout the body. In autoimmune diseases, the **immune system** (page 255) attacks the body instead of protecting it. Kidney, lung,

and vascular damage are potential problems resulting from SLE.

The cause of SLE is unknown, though 90% of cases occur in women of childbearing age. Several drugs, such as procainamide, hydralazine, methyldopa, and chlorpromazine, may create SLE-like symptoms. Environmental pollution and industrial emissions were associated with an increased risk of SLE in one study.<sup>1</sup> In one reported case, **zinc** (page 614) supplementation appears to have aggravated drug-induced SLE.<sup>2</sup> Ultraviolet radiation from sun exposure is a commonly recognized trigger of the skin manifestations of lupus.<sup>3</sup> Some environmental chemicals such as hydrazine<sup>4</sup> and food dyes such as tartrazine<sup>5</sup> may be environmental triggers of SLE in susceptible people.

Risk factors include a family history of SLE, other collagen diseases or **asthma** (page 30),<sup>6</sup> menstrual irregularity,<sup>7</sup> beginning menstruation at age 15 or later,<sup>8</sup> exposure to toxic chemicals,<sup>9</sup> and low blood levels of **antioxidant** (page 467) nutrients, such as **vitamin A** (page 595) and **vitamin E** (page 609), or **beta-carotene** (page 469).<sup>10</sup> Free radicals are thought to promote SLE.<sup>11</sup>

Discoid lupus erythematosus (DLE) is a milder form of lupus that affects the skin. Like SLE, it's not known what causes DLE, though sun exposure may trigger the first outbreak. DLE is most common among women in their thirties.

#### CHECKLIST FOR SYSTEMIC LUPUS ERYTHEMATOSUS

Rating	Nutritional Supplements	Herbs
★★★	<b>DHEA</b> (page 503) <b>Fish oil</b> (page 514) (EPA/ <b>DHA</b> [page 509])	<i>Tripterygium wilfordii</i>
★★☆	<b>Pantothenic acid</b> (page 568) <b>Vitamin E</b> (page 609)	<b>Astragalus</b> (page 631)

#### What are the symptoms of SLE?

Symptoms include decreased energy, weakness, fever, nausea, **diarrhea** (page 163), muscle and joint pain, chest pain, **bruising** (page 84), loss of appetite, weight loss, and a red, butterfly-shaped rash across the nose and cheeks. In addition, people with SLE may have symptoms of mouth sores, joint swelling, hair loss, changes in personality, seizures, and a coin-shaped, red skin rash elsewhere on the body that is aggravated by

sunlight. Kidney, lung, and blood-vessel damage are potentially life-threatening manifestations of SLE.

#### Medical treatments

Prescription drug treatment includes cortisone-like drugs, such as prednisone (Deltasone, Orasone), methylprednisolone (Medrol), and dexamethasone (Decadron); the hormone dehydroepiandrosterone (**DHEA** [page 503]); immunosuppressants, such as azathioprine (Imuran), chlorambucil (Leukeran), cyclosporine (Sandimmune), methotrexate (Rheumatrex), and cyclophosphamide (Cytoxan); and the antimalarial drugs hydroxychloroquine (Plaquenil) and chloroquine (Aralen). The goal of therapy is to suppress symptoms and relieve discomfort.

#### Dietary changes that may be helpful

An isolated case of someone with SLE improving significantly after the introduction of a vegetarian diet has been reported.<sup>12</sup> In Japan, women who frequently ate fatty meats, such as beef and pork, were reported to be at higher risk for SLE compared with women eating little of these foods.<sup>13</sup> Consuming fewer calories, less fat, and foods low in **phenylalanine** (page 568) and **tyrosine** (page 465) (prevalent in high protein foods, such as meat and dairy) might be helpful, according to animal and preliminary human studies.<sup>14</sup>

Foods high in omega-3 fatty acids, such as fish and **flaxseed** (page 517), may decrease lupus-induced inflammation. In one preliminary trial, nine people with kidney damage due to SLE were fed increasing amounts of flaxseed for a total of 12 weeks.<sup>15</sup> After examining the results, researchers concluded that 30 grams per day was the optimal intake for improving kidney function, decreasing inflammation, and reducing **atherosclerotic** (page 38) development. Flaxseeds also contain **antioxidants** (page 467), potentially helpful to those with SLE.<sup>16</sup>

To date, all studies on **fish oil** (page 514) have used supplements and not fish (see below). Nonetheless, many doctors recommend that SLE patients eat several servings of fatty fish each week.

Spanish researchers discovered that people with SLE tend to have more **allergies** (page 14), including food allergies, than do healthy people or even people with other autoimmune diseases.<sup>17</sup> While one study reported that drinking milk was associated with a decrease in SLE risk,<sup>18</sup> other investigations point to both beef<sup>19</sup> and dairy<sup>20</sup> as foods that might trigger allergic reactions in some people with SLE. Casein, the main protein in

cow's milk, has immune-stimulating properties.<sup>21</sup> This might explain why some people with SLE have been reported to be intolerant of milk products. Although there are several published case reports of patients with SLE showing clinical improvement after avoiding allergenic foods, additional research is needed to determine the importance of allergies as a cause of SLE. People with SLE who wish to explore whether allergies are contributing to their condition should consult a doctor.

**Alfalfa** (page 623) seeds and sprouts contain the amino acid L-canavanine, which provokes a lupus-like condition in monkeys<sup>22</sup> and possibly humans.<sup>23</sup> For this reason, some doctors recommend that people with SLE should avoid these foods. Cooking alfalfa seeds has been reported to erase this effect.<sup>24</sup>

#### Lifestyle changes that may be helpful

In preliminary research, smoking has been linked to significantly increased risk of developing SLE, while drinking alcohol has been associated with a decrease in risk.<sup>25</sup> The importance of these associations remains unclear, though an increased risk for many other diseases has been definitively linked to excessive consumption of alcohol.

#### Nutritional supplements that may be helpful

Low blood levels of the hormone DHEA and the related compound DHEA-sulfate have been associated with more severe symptoms in people with SLE.<sup>26</sup> Preliminary trials have suggested that 50 to 200 mg per day DHEA improved symptoms in people with SLE.<sup>27, 28</sup> One double-blind trial of women with mild to moderate SLE found that 200 mg of **DHEA** (page 503) per day improved symptoms and allowed a greater decrease in prednisone use,<sup>29</sup> but a similar trial in women with severe SLE found only insignificant benefits.<sup>30</sup>

Experts have concerns about the use of **DHEA** (page 503), particularly because there are no long-term safety data. Side effects at high intakes (50 to 200 mg per day) in one 12-month trial included acne (in over 50% of people), increased facial hair (18%), and increased perspiration (8%). Less common problems reported with DHEA supplementation were breast tenderness, weight gain, mood alteration, headache, oily skin, and menstrual irregularity.<sup>31</sup>

High amounts of DHEA have caused cancer in animals.<sup>32, 33</sup> Although anticancer effects of DHEA have also been reported,<sup>34</sup> they involve trials using animals that do not process DHEA the way humans do, so these positive effects may have no relevance for people.

Links have begun to appear between higher DHEA levels and risks of prostate cancer in humans.<sup>35</sup> At least one person with **prostate cancer** (page 371) has been reported to have had a worsening of his cancer despite feeling better while taking very high amounts (up to 700 mg per day) of DHEA.<sup>36</sup> While younger women with breast cancer may have low levels of DHEA, postmenopausal women with **breast cancer** (page 65) appear to have high levels of DHEA, which has researchers concerned.<sup>37</sup> These cancer concerns make sense because DHEA is a precursor to testosterone (linked to prostate cancer) and estrogen (linked to breast cancer). Until more is known, it would be prudent for people with breast or prostate cancer or a family history of these conditions to avoid supplementing with DHEA. Preliminary evidence has also linked higher DHEA levels to ovarian cancer in women.<sup>38</sup>

Some doctors recommend that people taking DHEA have liver enzymes measured routinely. Anecdotes of DHEA supplementation (of at least 25 mg per day) leading to **heart arrhythmias** (page 93) have appeared.<sup>39</sup> At only 25 mg per day, DHEA has lowered HDL cholesterol while increasing insulin-like growth factor (IGF).<sup>40</sup> Decreasing HDL could increase the risk of **heart disease** (page 98). Increasing IGF might increase the risk of breast cancer.

The omega-3 fatty acids in **fish oil** (page 514)—eicosapentaenoic acid (EPA) and docosahexaenoic acid (**DHA** [page 509])—decrease inflammation. Supplementation with EPA and DHA has prevented autoimmune lupus in animal research.<sup>41</sup> In a double-blind trial, 20 grams of fish oil daily combined with a low-fat diet led to improvement in 14 of 17 people with SLE in 12 weeks.<sup>42</sup> Smaller amounts of fish oil have led to only temporary improvement in another double-blind trial.<sup>43</sup> People wishing to take such a large amount of fish oil should first consult with a doctor.

**Antioxidant** (page 467) levels have been reported to be low in people with SLE, though this finding was not statistically significant in one trial.<sup>44</sup> When animals are fed antioxidant-deficient diets, they develop a condition similar to SLE; supplementation with antioxidants, such as **vitamin C** (page 604), **vitamin E** (page 609), **beta-carotene** (page 469), and **selenium** (page 584), has helped animals with existing SLE.<sup>45</sup> It remains unclear whether antioxidant supplementation would have a positive effect on people with SLE.

Some preliminary evidence suggests that **vitamin E** (page 609) might help people with discoid lupus erythematosus (DLE). Two doctors reported good to ex-

cellent results by giving 800–2,000 IU of vitamin E per day to eight people with DLE.<sup>46, 47</sup> According to these physicians, lower amounts of vitamin E did not work as well. In another small trial, vitamin E, also given in high amounts, had no effect.<sup>48</sup> Unlike with DLE, there appear to be no reports on the effects of vitamin E in people with SLE.

In one preliminary report, 250,000 IU beta-carotene per day cleared up all facial rashes in as little as one week for three people with DLE.<sup>49</sup> However, another study involving 26 people (19 with DLE and seven with SLE) found that using an even higher intake (400,000 IU per day) for an average of five and a half months was ineffective.<sup>50</sup> Research has not yet supported the use of beta-carotene for people with SLE.

Preliminary research suggests that **pantothenic acid** (page 568), when taken together with vitamin E, may help those with DLE. In one trial, taking 10 to 15 grams of pantothenic acid per day with 1,500 to 3,000 IU of vitamin E per day for as long as 19 months helped 67 people with DLE.<sup>51</sup> Pantothenic acid by itself for shorter periods of time in lower amounts has been reported to fail.<sup>52</sup> The amounts of pantothenic acid and vitamin E used in the first trial are very high and should not be taken without the supervision of a physician.

In a preliminary study, supplementation with pycnogenol was said to be beneficial in a small group of people with SLE.<sup>53</sup> However, in this study, the pycnogenol and placebo groups were not comparable; moreover, according to some criteria, the placebo group actually fared better than the treatment group. Until a better designed study is performed, pycnogenol cannot be recommended as a treatment for lupus.

#### *Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

#### **Herbs that may be helpful**

Preliminary evidence indicates that some Chinese herbs may help those with SLE. In one preliminary trial, a formula composed of 17 Chinese herbs was given to people with SLE.<sup>54</sup> Of the people who were also taking cortisone, 92% improved, but 85% of those taking the herbs alone also benefited. People with SLE-induced kidney damage given a combination of conventional drugs plus a Chinese herbal formula for six months did significantly better than those given the drugs alone.<sup>55</sup>

Various Chinese herbs have prolonged survival in animals with SLE.<sup>56</sup>

One of these Chinese herbs, *Tripterygium wilfordii*, is thought to benefit those with SLE or DLE by both suppressing **immune function** (page 255) and acting as an anti-inflammatory agent. When people with DLE took 30 to 45 grams of tripterygium per day for two weeks in a preliminary trial, most experienced some degree of improvement, including reduction or disappearance of skin rashes.<sup>57</sup> Skin rashes in eight people completely cleared up, while in ten people over 50% of the rash improved.

A preliminary trial gave the same dose of tripterygium to people with SLE.<sup>58</sup> After one month, 54% experienced relief from symptoms such as joint pain and malaise.

Use of the crude tripterygium herb is not recommended, and people interested in using it should work with their doctor to obtain the specially prepared and standardized extracts used in clinical studies. Because of potential side effects, people with SLE or DLE should consult with a doctor experienced in herbal medicine before using this herb. In the first two studies summarized, less than 8% of women with DLE and approximately one-third of women with SLE experienced **amenorrhea** (page 22) (cessation of menstruation) after taking tripterygium. Other side effects ranged from stomach upset or pain, to nausea, loss of appetite, dizziness, and increased facial coloring. Both studies found that these effects subsided with time once people stopped using the herb. However, some reports have found more serious side effects and even death with use of tripterygium.<sup>59</sup>

**Pregnant** (page 363) women should not use the herb.

Finally, a report suggests that long-term use (over five years) of tripterygium significantly reduced bone density in women taking it to treat lupus.<sup>60</sup> While this loss of bone density was less severe than that found with long-term use of prednisone, lupus patients should have their bone density checked at yearly intervals by their doctor when using the herb.

One Chinese preliminary trial also found that **astragalus** (page 631) could decrease overactive immune function in people with systemic lupus erythematosus.<sup>61</sup> However, much more research is needed to know whether astragalus is safe in lupus or any other autoimmune disease.

#### *Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

## TARDIVE DYSKINESIA

Tardive Dyskinesia (TD) is a condition of abnormal, repetitive, uncontrollable movements that develop after a long-term use of so-called antipsychotic medications used to treat **schizophrenia** (page 393) and related psychiatric disorders. The term “tardive” (which means “late”) is used because the condition appears only after long-term use of these drugs, which include chlorpromazine (Thorazine), thioridazine (Mellaril), and trifluoperazine (Stelazine). Dyskinesia means “abnormal movement.”

The uncontrollable movements of TD can interfere greatly with a person’s quality of life. TD may gradually diminish in severity after the medication is discontinued, but all too often the problem is permanent, persisting after withdrawal from the drugs that caused the condition. Conventional treatment for TD is unsatisfactory, so prevention is considered crucial. It is important that people requiring antipsychotic drugs be given the lowest effective dose and that treatment be discontinued as soon as it is feasible.

### CHECKLIST FOR TARDIVE DYSKINESIA

Rating	Nutritional Supplements	Herbs
★★★	<b>Vitamin E</b> (page 609)	
★★☆	<b>Choline</b> (page 546) <b>Lecithin</b> (page 546) <b>Manganese</b> (page 553) <b>Melatonin</b> (page 555)	
★☆☆	<b>Branched-chain amino acids</b> (page 479) (BCAA) <b>DMAE</b> (page 508) <b>Evening primrose oil</b> (page 511) <b>Vitamin B-complex</b> (page 603) <b>Vitamin B<sub>3</sub></b> (page 598) (niacin or niacinamide) <b>Vitamin B<sub>6</sub></b> (page 600) <b>Vitamin C</b> (page 604)	

### What are the symptoms of tardive dyskinesia?

Symptoms of TD include repetitive and involuntary movements (tics), most often of the facial muscles and tongue (such as lip smacking), although any muscle in the body can be affected (e.g., moving legs back and

forth). Symptoms may be mild or severe and can interfere with eating and walking.

### Medical treatments

Prescription drugs used to treat tardive dyskinesia include trihexyphenidyl (Artane, Trihexy), benztropine (Cogentin), and dopamine-depleting agents, such as reserpine.

Electroconvulsive therapy (electrical current applied to the brain) may be administered in severe cases. Healthcare providers may recommend discontinuing the use of antipsychotic drugs if possible.

### Nutritional supplements that may be helpful

**Vitamin E** (page 609) has been found in a number of studies to reduce the severity of TD. In a double-blind trial, people with TD were randomly assigned to receive vitamin E (800 IU per day for two weeks and 1,600 IU per day thereafter) or a placebo. Vitamin E was significantly more effective than placebo in reducing involuntary movements.<sup>1</sup> An uncontrolled study of 20 people with TD reported that 1,600 IU of vitamin E per day may be the optimal amount;<sup>2</sup> this large amount should be supervised by a healthcare practitioner. Other studies have also found that vitamin E supplements reduce the severity of TD.<sup>3, 4, 5</sup> Two studies failed to show a beneficial effect of vitamin E.<sup>6, 7</sup> However, the people in those studies had been receiving neuroleptics for at least ten years, and research has shown that vitamin E is most effective when started within the first five years of neuroleptic treatment.<sup>8, 9</sup>

**Choline** (page 546) and **lecithin** (page 546) have both been used for people with TD. While some studies have shown a beneficial effect,<sup>10, 11, 12</sup> others have reported variable improvement<sup>13</sup> or no improvement.<sup>14</sup> In a small, two-week, double-blind trial, people with TD were given 25 grams of lecithin twice a day, or a matching placebo. All participants experienced significant improvement of symptoms.<sup>15</sup>

**Dimethylaminoethanol** (page 508) (DMAE) is a natural choline precursor. Although some preliminary data suggested that DMAE could decrease TD symptoms,<sup>16</sup> most studies show that DMAE is no more effective than placebo for TD.<sup>17</sup>

One doctor has found that administering the trace mineral **manganese** (page 553) (15 mg per day) can prevent the development of TD and that higher amounts (up to 60 mg per day) can reverse TD that has

already developed.<sup>18</sup> Other researchers have reported similar improvements with manganese.<sup>19, 20</sup>

Several people have experienced an improvement in TD while taking **evening primrose oil** (page 511) (EPO).<sup>21</sup> In a double-blind study, however, supplementing with EPO (12 capsules per day) resulted only in a minor, clinically insignificant improvement.<sup>22</sup>

Preliminary research has linked TD to the inability of the body to metabolize the amino acid **phenylalanine** (page 568). Supplementing with **branched-chain amino acids** (page 479) (BCAA), including valine, isoleucine, and leucine, could reduce excess phenylalanine in people with this disorder. In one trial, researchers examined the effects of BCAA supplementation in people with TD (from 150 mg per 2.2 pounds body weight, up to 209 mg per 2.2 pounds body weight) after breakfast and one hour before lunch and dinner for two weeks.<sup>23</sup> The BCAA mixture included equal parts valine and isoleucine plus 33% more leucine than either of the other two amino acids. Of nine people treated, six experienced at least a 58% reduction in symptoms, and all nine had a least a 38% decrease.

During a ten-year period, doctors at the North Nassau Mental Health Center in New York treated approximately 11,000 people with **schizophrenia** (page 393) with a megavitamin regimen that included **vitamin C** (page 604) (up to 4 grams per day), **vitamin B<sub>3</sub>** (page 598)—either as niacin or niacinamide—(up to 4 grams per day), **vitamin B<sub>6</sub>** (page 600) (up to 800 mg per day), and **vitamin E** (page 609) (up to 1,200 IU per day). During that time, not a single new case of TD was seen, even though many of the people were taking neuroleptic drugs.<sup>24</sup> Another psychiatrist who routinely used **niacinamide** (page 598), vitamin C, and **vitamin B-complex** (page 603) over a 28-year period rarely saw TD develop in her patients.<sup>25</sup> Further research is needed to determine which nutrients or combinations of nutrients were most important for preventing TD. The amounts of niacinamide and vitamin B<sub>6</sub> used in this research may cause significant side effects and may require monitoring by a doctor.

In a double-blind trial, supplementation with 10 mg of **melatonin** (page 555) each night for six weeks reduced abnormal movements by 23.8% in patients with TD, compared with 8.4% in the placebo group, a statistically significant difference.<sup>26</sup>

#### *Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

## TENDINITIS

Tendinitis is a condition where a tendon or the connective tissue that surrounds the tendon becomes inflamed.

This is often due to overuse (e.g., repetitive work activities), acute injury, or excessive exercise. People who are at higher risk of developing tendinitis include athletes, manual laborers, and computer keyboard users. Occasionally, tendinitis may be due to diseases that affect the whole body, such as **rheumatoid arthritis** (page 387) or **gout** (page 208).

The most common sites of tendinitis are the shoulder, elbow, forearm, thumb, hip, hamstring muscles (in the back of the upper leg), and Achilles tendon (behind the ankle).<sup>1</sup>

#### CHECKLIST FOR TENDINITIS

Rating	Nutritional Supplements	Herbs
★★★	<b>DMSO</b> (page 508) (topical)	
★★☆	<b>Bromelain</b> (page 481) <b>Proteolytic enzymes</b> (page 506)	

#### **What are the symptoms of tendinitis?**

People with tendinitis may have symptoms, which appear after injury or overuse, including swelling, redness, tenderness, and sharp pain in the affected area, which is worsened with movement or pressure.

#### **Medical treatments**

Over the counter pain medications, such as aspirin (Bayer, Ecotrin, Bufferin), acetaminophen (Tylenol), and ibuprofen (Motrin, Advil), are routinely recommended to relieve minor pain and reduce inflammation. Topical methyl salicylate (Icy Hot, Ben-Gay), trolamine salicylate (Aspercreme), and combination counterirritant products (Maximum Strength Flexall 454) may be beneficial to relieve pain.

Prescription strength nonsteroidal anti-inflammatory drugs (NSAIDs), such as celecoxib (Celebrex), valdecoxib (Bextra), ibuprofen (Motrin), naproxen (Anaprox, Naprosyn), and indomethacin (Indocin), may be necessary to treat inflammation and pain. Acetaminophen combined with codeine (Tylenol with Codeine) or hydrocodone (Vicodin) may be used to treat moderate pain.

Treatment may include local injections of steroids such as dexamethasone (Decadron-LA), methylprednisolone (Depo-Medrol), and hydrocortisone (Solu-Cortef), or anesthetics such as lidocaine (Xylocaine), as well as immobilization and controlled physical therapy.

#### Lifestyle changes that may be helpful

Many people suffer from tendinitis as a result of their work environment. Studies have shown that tendinitis of the wrist, hands, and fingers are often caused by repetitive work and physical stress.<sup>2, 3, 4</sup> Physical changes to the work environment, such as setting up the work station so that the body is in a balanced, un-twisted position, minimizing the need to use excessive force, avoiding overuse of any one joint, changing positions frequently, and allowing for rest periods, have all been shown to diminish symptoms of lower arm tendinitis.<sup>5</sup> One study of computer workers with arm and wrist tendinitis found that using an ergonomic keyboard versus a standard keyboard reduced the severity of pain and improved hand function after six months of use.<sup>6</sup>

#### Nutritional supplements that may be helpful

DMSO (page 508), or dimethyl sulfoxide, has a long history as a topical anti-inflammatory agent. One double-blind trial used a 10% DMSO gel topically on patients with tendinitis of the elbow and shoulder and found that it significantly reduced pain and inflammation in each joint.<sup>7</sup> Other preliminary<sup>8, 9</sup> and double-blind<sup>10, 11</sup> trials found DMSO to be effective in treating tendinitis, but one double-blind trial found no difference between the effects of a 70% DMSO solution and a 5% DMSO placebo solution.<sup>12</sup> Certain precautions must be taken when applying DMSO, and it should only be used under the guidance of a qualified healthcare professional.

Alternative healthcare practitioners frequently recommend **proteolytic enzymes** (page 506) for various minor injuries. Research demonstrates that these enzymes are well absorbed when taken by mouth,<sup>13, 14</sup> and preliminary<sup>15, 16, 17, 18</sup> and double-blind<sup>19, 20, 21, 22</sup> trials have shown their effectiveness for reducing pain and swelling associated with various injuries and for speeding up the healing process. Unfortunately, many of these studies did not specifically identify the patients' injury, so it is unclear whether the positive results included improvements in tendinitis.

**Bromelain** (page 481), a proteolytic enzyme, is an anti-inflammatory agent and for this reason is helpful in healing minor injuries, particularly **sprains and strains** (page 412), muscle injuries, and the **pain** (page 338), swelling, and tenderness that accompany sports injuries.<sup>23, 24, 25</sup>

#### *Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

#### Holistic approaches that may be helpful

Acupuncture may be helpful for treating tendinitis. A controlled trial compared acupuncture to sham (fake) acupuncture in people with shoulder tendinitis and found that acupuncture treatment produced significantly higher scores on a combined measurement of pain, ability to perform daily activities, ability to move shoulder without pain, and strength.<sup>26</sup> This study also reported that the beneficial effects of acupuncture continued for at least three months following treatment. Another controlled study found traditional "deep" acupuncture more effective than superficial acupuncture for tennis elbow immediately after a series of ten treatments, but at 3 to 12 months' follow up, both treatment groups had improved similarly.<sup>27</sup> A third controlled study found no benefit from ten treatments of laser acupuncture for tennis elbow.<sup>28</sup>

Certain treatments used by physicians and other healthcare practitioners have been shown to be effective for tendinitis. In a controlled trial, patients with tendinitis of the shoulder received 24 treatments over six weeks of either ultrasound or a sham treatment.<sup>29</sup> Ultrasound resulted in considerable improvement in pain level and overall quality of life, but many of the patients had their original symptoms return after nine months. The use of ultrasound for tennis elbow has not been validated, according to a systematic review of controlled studies.<sup>30</sup> One controlled trial compared the effects of ultrasound alone to ultrasound plus a topical steroid medication (a process known as phonophoresis, where ultrasound is used to drive a substance into the skin).<sup>31</sup> Both of these treatments were given three times per week for three weeks and both produced similar reductions in pain and tenderness.

Preliminary studies have suggested that daily use of TENS (transcutaneous electrical nerve stimulation) for one to two weeks reduces or eliminates pain in patients with tendinitis.<sup>32, 33</sup> Controlled studies are needed to confirm these findings.

## TENSION HEADACHE

A tension-type headache is common and typically experienced as a dull, non-throbbing pain in the back of the neck or in a “headband” distribution.<sup>1</sup> It may be associated with tender nodules in the neck called trigger-points,<sup>2</sup> or with tenderness in the muscles around the head.<sup>3</sup>

### CHECKLIST FOR TENSION HEADACHE

Rating	Nutritional Supplements	Herbs
★★★	L-5-hydroxytryptophan (page 459) (5-HTP)	Peppermint (page 726) oil (topical)

### What are the symptoms of tension headaches?

People with a headache may have symptoms including uncomfortable sensations described as pain, throbbing, aching, dullness, heaviness, and tightness in the head. People with a headache may also experience discomfort that is often worsened by movement or pressure and may be associated with irritability, problems sleeping, and fatigue.

### Medical treatments

Over the counter pain medications, such as aspirin (Bayer, Ecotrin, Bufferin), acetaminophen (Tylenol), and ibuprofen (Motrin, Advil), are routinely recommended to relieve minor pain from tension headaches.

Healthcare practitioners might recommend application of moist heat to tight neck muscles and light massage.

### Lifestyle changes that may be helpful

Tension-type headaches often occur more frequently and may become more severe during or following times of mental or emotional stress.<sup>4, 5, 6</sup> Several controlled studies have found tension-type headache sufferers to report higher levels of stress,<sup>7, 8, 9</sup> and to have significantly higher levels of **depression** (page 145) or **anxiety** (page 30),<sup>10, 11, 12</sup> significantly greater levels of suppressed anger,<sup>13</sup> or significantly greater muscle tension<sup>14, 15</sup> than those without headaches. Minimizing stress and getting enough sleep and regular exercise are often recommended to people with tension-type headaches. However, no research has investigated the effectiveness of these lifestyle changes.

One controlled study that included patients with muscle-contraction headache as well as other types of headache, revealed that smokers had significantly more severe headache episodes than nonsmokers.<sup>16</sup> Although other studies have not found an association between smoking and headaches, stopping smoking is always a good idea for many health reasons.

### Nutritional supplements that may be helpful

**L-5-hydroxytryptophan** (page 459) (5-HTP) may be helpful for tension-type headaches. A recent double-blind study of adults with chronic tension-type headaches found 300 mg per day of 5-HTP reduced the number of headache days by 36%, but this was not significantly different from the 29% reduction in the placebo group.<sup>17</sup> (Headaches often improve significantly even when an inactive [placebo] treatment is given).<sup>18</sup> Headache severity was also similarly reduced by either 5-HTP or placebo. In this study, 5-HTP was significantly superior to placebo only in reducing the need for pain-relieving medications during headaches. Previous double-blind research studied 5-HTP in groups of patients suffering from many different types of headache, including some with tension-type headaches. Results from these studies also found substantial, but nonsignificant benefits of 5-HTP compared with placebo using either 400 mg per day in adults<sup>19</sup> or 100 mg per day in children.<sup>20</sup>

### Are there any side effects or interactions?

Refer to the individual supplement for information about any side effects or interactions.

### Herbs that may be helpful

A preliminary report suggested that **peppermint** (page 726) oil has relaxing and pain relieving effects, and may be useful as a topical remedy for tension-type headache.<sup>21</sup> In a double-blind study, spreading a 10% peppermint oil solution across the temples three times over a 30-minute period was significantly better than placebo and as effective as acetaminophen in reducing headache pain.<sup>22</sup> Similar use of an ointment combining menthol and other oils related to peppermint oil was also as effective as pain relieving medication and superior to placebo in another double-blind study.<sup>23</sup>

### Are there any side effects or interactions?

Refer to the individual herb for information about any side effects or interactions.

### Holistic approaches that may be helpful

Studies treating tension-type headache with acupuncture have had mixed results.<sup>24</sup> Two controlled trials of acupuncture compared to “fake” acupuncture found either significantly more pain reduction from real acupuncture<sup>25</sup> or no difference between the two treatments.<sup>26</sup> Two trials comparing acupuncture to traditional physical therapy (relaxation techniques, self-massage, cold therapy, transcutaneous electrical nerve stimulation [TENS], stretching, and/or preventive education) in tension-type headache patients found similar improvements from either treatment.<sup>27, 28</sup> Three controlled acupuncture trials treated patients with various types of headaches, including tension headache. Two of these studies,<sup>29, 30</sup> but not the third,<sup>31</sup> found acupuncture significantly more effective.

Two preliminary studies<sup>32, 33</sup> reported benefits from using finger pressure on specific acupuncture points (acupressure) to relieve tension-type headache pain in some patients. However, no controlled research on this approach has been done.

Spinal manipulation may also help some tension-type headache sufferers. Several preliminary studies report reduction in frequency and severity of tension-type headaches with spinal manipulation.<sup>34, 35, 36, 37, 38, 39</sup> A controlled trial compared spinal manipulation to drug therapy for tension-type headaches.<sup>40</sup> During the treatment period, both groups improved at similar significant rates, although the manipulation group complained of far fewer side effects. After a month following the end of treatment, only the manipulation group showed continued improvement. In another controlled trial, spinal manipulation resulted in fewer headache hours each day, decreased use of analgesics, and less intense pain per episode compared with massage.<sup>41</sup> A third controlled study reported that spinal manipulation with muscle massage was equally as effective as massage plus a “fake” laser treatment, suggesting that manipulation did not provide additional benefit.<sup>42</sup>

As mentioned above, two controlled studies found physical therapy (relaxation techniques, self-massage, cold therapy, TENS, stretching, and/or preventive education) as useful as acupuncture in significantly reducing headache pain and frequency.<sup>43, 44</sup> A preliminary study also found that physical therapy, consisting of posture education, home exercises, massage, and stretching of the neck muscles, significantly improved tension headaches up to 12 months after

treatment ended.<sup>45</sup> Another preliminary study of massage, including deep penetrating techniques, reported significantly decreased pain in patients with chronic tension headache and neck pain.<sup>46</sup> A controlled study of headache patients with muscle spasm in the neck and shoulders found that adding TENS to physical therapy (consisting of heat packs, massage, and ultrasound) brought a significantly faster and greater decline in headaches than physical therapy alone.<sup>47</sup>

Several controlled trials utilizing electromyogram (EMG)-biofeedback (which teaches people how to mentally relax their neck or head muscles) have shown this treatment to be helpful in about 50% of tension-type headache sufferers, both in adults<sup>48, 49, 50, 51, 52</sup> and in children and adolescents.<sup>53, 54</sup> Progressive muscle relaxation is another muscle relaxation technique that has significantly reduced tension-type headache in controlled studies of adults,<sup>55, 56</sup> and children and adolescents.<sup>57, 58</sup>

Relaxation with techniques for stress management was found to be significantly better than drug therapy in a controlled trial of chronic tension-type headache sufferers,<sup>59</sup> although about half of all subjects continued to have headaches three to four days per week after the end of treatment.

Hypnotherapy was found to significantly reduce headache intensity and duration in chronic tension-type headache sufferers in one controlled trial.<sup>60</sup>

A large controlled study of tension headache patients compared relaxation therapies (including progressive muscle relaxation, hypnosis, and cognitive psychotherapy) with EMG-biofeedback, and found biofeedback to be significantly more effective than relaxation in decreasing headache pain and frequency.<sup>61</sup>

In a controlled trial, therapeutic touch, a type of hands-on healing, was found to significantly reduce tension headache pain for four hours following treatment.<sup>62</sup> No further research has been done on this approach.

Reflexology, a specific treatment involving massage of various reflex zones on the feet, has only been investigated as a treatment for tension-type headache in one preliminary trial.<sup>63</sup> A majority of people treated in this study reported being helped by this technique.

A controlled trial of homeopathy in headache patients, including tension-type headache, found no significant benefit of homeopathy compared to a placebo group.<sup>64</sup>

## TINNITUS

Rarely, tinnitus is due to an actual sound, such as blood rushing through an enlarged vein—a problem that requires medical treatment. More commonly the problem is due to nerve irritation from an unknown source or an underlying ear problem often induced by noise damage. The cause of tinnitus should be diagnosed by a doctor.

### CHECKLIST FOR TINNITUS (RINGING IN THE EARS)

Rating	Nutritional Supplements	Herbs
★★★	<b>Melatonin</b> (page 555) (insomnia-associated) <b>Zinc</b> (page 614) (for deficiency only)	
★★★	<b>Vitamin B<sub>12</sub></b> (page 601) (injection)	<b>Ginkgo biloba</b> (page 681) <b>Periwinkle</b> (page 727)

### What are the symptoms of tinnitus?

Symptoms may include hearing buzzing, roaring, ringing, whistling, or hissing sounds. These sounds may be intermittent, continuous, or pulsing. Tinnitus may interfere with normal activities and sleep, and there may be an associated decrease in the ability to hear conversation or other sounds in the environment.

### Medical treatments

Treatment is typically directed at any underlying medical condition. In some cases, doctors recommend the use of a tinnitus masker, which is a hearing device that produces a sound that is more tolerable than the tinnitus. In addition, doctors may suggest the use of earplugs in the presence of loud noises to prevent damage to the ear.

### Dietary changes that may be helpful

**Ménière's disease** (page 308) (a condition characterized by tinnitus, **vertigo** [page 441], and hearing loss) is reportedly associated with various metabolic abnormalities, including elevations of serum **cholesterol** (page 223) and/or **triglycerides** (page 235) and abnormal regulation of blood sugar. In one trial, people with Ménière's disease who replaced refined carbohydrates in

their diet with foods high in **fiber** (page 512) and complex carbohydrates frequently experienced an improvement or disappearance of their tinnitus.<sup>1</sup>

### Nutritional supplements that may be helpful

**Zinc** (page 614) supplements have been used to treat people who had both tinnitus and hearing loss (usually age-related). Of those who had initially low blood levels of zinc, about 25% experienced an improvement in tinnitus after taking zinc (90–150 mg per day for three to six months).<sup>2</sup> Such large amounts of zinc should be monitored by a doctor. Two controlled clinical trials<sup>3, 4</sup> found no benefit from zinc supplementation (66 mg per day in one double-blind trial) in people with tinnitus. However, participants in these studies were not zinc deficient. Preliminary research suggests that zinc supplementation is only helpful for tinnitus in people who are zinc deficient.<sup>5</sup> A doctor can measure blood levels of zinc.

In a double-blind trial, **melatonin** (page 555) supplementation (3 mg taken nightly) improved the symptoms of tinnitus.<sup>6</sup> Although improvement did not reach statistical significance for all participants, the results were significant in those who reported more severe symptoms (such as two-sided vs. one-sided tinnitus). Among participants who had difficulty sleeping due to tinnitus, 47% of those who took melatonin reported sleep improvement after one month, compared with only 20% of those who took placebo.

People exposed to loud noise on the job who develop tinnitus are commonly deficient in **Vitamin B<sub>12</sub>** (page 601).<sup>7</sup> Intramuscular injections of vitamin B<sub>12</sub> reduced the severity of tinnitus in some of these people. Injectable vitamin B<sub>12</sub> is available only by prescription. The effect of oral vitamin B<sub>12</sub> on tinnitus has not been studied.

### Are there any side effects or interactions?

Refer to the individual supplement for information about any side effects or interactions.

### Herbs that may be helpful

Lesser **periwinkle** (page 727) (*Vinca minor*) contains a compound known as vincamine. Extracts containing vincamine have been used in Germany to help decrease tinnitus.<sup>8</sup> Preliminary clinical trial data show that vinpocetine, a semi-synthetic version of vincamine, can help reduce symptoms in people whose tinnitus is due to poor blood flow.<sup>9</sup> Because these extracts are not widely available outside of Germany, consult with a

doctor knowledgeable in botanical medicine about obtaining them.

**Ginkgo biloba** (page 681) has been used to treat tinnitus, with mixed results.<sup>10</sup> The largest placebo-controlled trial to date failed to find any effect of 150 mg per day of ginkgo extract in people with tinnitus.<sup>11</sup> Two smaller, controlled trials have found that standardized ginkgo extract (120 mg per day, containing 24% flavone glycosides and 6% terpene lactones), was effective at relieving the symptoms of tinnitus.<sup>12, 13</sup> One trial failed to find ginkgo beneficial, but used less than 30 mg of ginkgo extract per day, an amount unlikely to have any therapeutic effect.<sup>14</sup>

#### *Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

#### **Holistic approaches that may be helpful**

Acupuncture has been studied as a treatment for tinnitus in several controlled trials. Preliminary trials have reported improvement in symptoms of tinnitus following acupuncture treatment, but this relief was either not permanent or did not reach statistical significance.<sup>15</sup> Most trials have shown no advantage of acupuncture treatment over placebo for the treatment of tinnitus.<sup>16, 17, 18, 19, 20, 21, 22</sup> A review of clinical trials concluded that acupuncture is not an effective treatment for tinnitus.<sup>23</sup>

## TOOTH DECAY

Tooth decay is the gradual breakdown of the tooth, beginning with the enamel surface and eventually progressing to the inner pulp.

Tooth decay is caused by acids produced by certain mouth bacteria in dental plaque. Factors that affect this process include oral hygiene, diet, meal frequency, saliva production, and heredity. Teeth with significant decay are said to have caries, or cavities.

#### **What are the symptoms of tooth decay?**

People with tooth decay may have tooth pain, including sensitivity to cold food and drinks.

#### **Medical treatments**

Over the counter products containing fluoride (Gel Kam, ACT) may help prevent tooth decay.

Prescription strength fluoride toothpaste (Prevident)

may be prescribed. Individuals living in communities without fluoridated water might be prescribed oral fluoride tablets or drops (Luride).

Treatment includes daily brushing of teeth with toothpaste (especially after meals), flossing, limiting sugar in the diet, and regular professional teeth cleanings by a dental hygienist. Dentists commonly apply fillings to dental cavities. Topical fluoride applications or sealants (plastic coatings that form a barrier between bacteria and the chewing surfaces of the teeth) may be recommended.

#### CHECKLIST FOR TOOTH DECAY

Rating	Nutritional Supplements	Herbs
★★★	<b>Fluoride</b> (page 519) <b>Lactobacillus GG</b> (page 575) <b>Xylitol</b> (page 614)	
★★☆	<b>Cod liver oil</b> (page 514) <b>Vitamin B<sub>6</sub></b> (page 600)	Black tea <b>Green tea</b> (page 686) ( <i>Camellia sinensis</i> ) Neem
★☆☆	<b>Sorbitol</b> <b>Strontium</b> (page 589)	

#### **Dietary changes that may be helpful**

It has been noted for over 50 years that the incidence of tooth decay is low in people of traditional rural societies, such as Eskimos and African Bantus. However, the incidence of cavities increases as their diets begin to include more “westernized” processed foods.<sup>1</sup> Although many different factors have been implicated in this observation, including refined flours,<sup>2, 3</sup> inactivation of vitamins by heating foods,<sup>4</sup> and sugar intake,<sup>5</sup> no single agent has been found responsible. Nevertheless, a diet high in whole grains and low in processed foods is a healthful choice that probably helps defend against tooth decay.

Sugar, especially sucrose (table sugar), appears to be required by the oral bacteria for the production of tooth decay. This finding has caused sugar to be widely blamed in the popular press as the primary cause of dental caries. However, caries incidence has recently declined in a time of increasing sugar intake.<sup>6</sup> This has led to a reevaluation of caries causation, and sugar is now understood to be only one of the factors in the development of tooth decay.<sup>7</sup> Nearly as important as the total

amount of sugar intake seems to be the consistency of the sugary foods and the length of time they are in contact with the teeth. Dry and sticky foods tend to stay in contact longer, causing more plaque formation.<sup>8</sup> Still, reduction of total dietary sugar is probably the most accepted dietary recommendation for the prevention of dental caries.<sup>9</sup>

Drinking fluoridated water (1 mg **fluoride** [page 519] per liter) has led to an estimated 40% to 60% reduction in dental caries in many cities in the United States and worldwide.<sup>10, 11</sup> While most experts believe water fluoridation to be associated with minimal risk,<sup>12</sup> others disagree. A minority of scientists believes fluoridation to be associated with an unacceptable risk of skeletal damage, including osteoporotic fractures and bone tumors, in exchange for a modest dental benefit.<sup>13</sup> Fluoride has topical action as well as whole-body effects,<sup>14</sup> suggesting that those who do not have access to fluoridated water can achieve some benefit with fluoride-containing toothpastes and mouthwashes. In areas without fluoridated water, a number of controlled trials have found oral use of chewable fluoride tablets (1 to 2 mg per day of fluoride)<sup>15, 16</sup> or fluoride mouthrinses (0.05% to 0.2% fluoride content)<sup>17, 18</sup> also reduce caries risk in children. Fluoride tablets<sup>19</sup> and mouthwash<sup>20</sup> have been found to be effective for caries prevention in young adults and the elderly. Tablets are slightly more effective than a mouthrinse for caries protection.<sup>21</sup> These products should not be used by young children (under three years of age), who might accidentally swallow dangerous amounts of fluoride.<sup>22</sup> The American Dental Association (ADA) recommends supplementing children in areas without fluoridated water with liquid fluoride drops,<sup>23</sup> but this should be done with the guidance of a dentist.

#### Lifestyle changes that may be helpful

The ADA recommends regular tooth brushing—daily brushing, ideally after each meal.<sup>24</sup> Although thorough brushing varies from person to person, five to ten strokes in each area should be adequate.<sup>25</sup> Toothpastes containing 1,000 to 2,500 ppm (1 to 2.5 mg per gram) of fluoride have been shown to reduce caries risk.<sup>26</sup>

A recent population survey found blood lead levels were associated with the amount of dental caries in children and adults. The authors estimated that lead exposure is responsible for roughly 10% of dental caries in young Americans.<sup>27</sup> For this and other health reasons, known and potential sources of lead exposure should be avoided. Common sources of lead exposure may

clude paint, foods grown near roadways, and water from lead pipes.<sup>28</sup>

#### Nutritional supplements that may be helpful

Test tube studies show that **vitamin B<sub>6</sub>** (page 600) increases growth of beneficial mouth bacteria and decreases growth of cavity-causing bacteria.<sup>29</sup> A double-blind study found that pregnant women who supplemented with 20 mg per day of vitamin B<sub>6</sub> had significantly fewer new caries and fillings during pregnancy.<sup>30</sup> Lozenges containing vitamin B<sub>6</sub> were more effective than capsules in this study, suggesting an important topical effect. Another double-blind study gave children oral lozenges containing 3 mg of vitamin B<sub>6</sub> three times per day for eight months, but reported only insignificant reductions in new cavities.<sup>31</sup>

In a double-blind study of children aged 1 to 6 years, supplementation with *Lactobacillus GG* five days a week in milk for seven months reduced the incidence of cavities by 49%, compared with un-supplemented milk.<sup>32</sup> The amount of *Lactobacillus* added to the milk was 5 to 10 x 10<sup>5</sup> CFU per ml.

Certain sugar substitutes appear to have anti-caries benefits beyond that of reducing sugar intake. Children chewing gum containing either **xylitol** (page 614) or sorbitol for five minutes five times daily for two years had large reductions in caries risk compared with those not chewing gum. Sorbitol is only slowly used by oral bacteria, and it produces less caries than sucrose.<sup>33</sup> Xylitol gum was associated with a slightly greater risk reduction than sorbitol gum.<sup>34</sup> Bacteria in the mouth do not ferment xylitol, so they cannot produce the acids that cause tooth decay from xylitol.<sup>35</sup> A double-blind study found 100% xylitol-sweetened gum was superior to gum containing lesser amounts or no xylitol.<sup>36</sup> Another study found xylitol-containing gums gave long-term protection against caries while sorbitol-only gum did not.<sup>37</sup> Other research has confirmed the anti-caries benefits of xylitol in various forms, including gum,<sup>38</sup> chewable lozenges, toothpastes, mouthwashes, and syrups.<sup>39</sup> Mothers typically transmit one of the decay-causing bacteria to their infant children, but a double-blind trial found that the children of mothers who regularly chewed xylitol-containing gum for 21 months, starting 3 months after delivery, had a greatly reduced risk of acquiring these bacteria,<sup>40, 41</sup> and also had 70% less tooth decay.<sup>42</sup>

One older controlled trial found that children given 3 teaspoons of **cod liver oil** (page 514) per day (containing roughly 800 IU of **vitamin D** [page 607]) for

an entire school year had over 50% fewer new cavities.<sup>43</sup> These promising results have not been followed up with modern placebo-controlled trials.

Levels of **strontium** (page 589) in the water supply have been shown to correlate with the risk of dental caries in communities with similar fluoride levels.<sup>44</sup> Compared with children with fewer cavities, enamel samples from children with high numbers of caries have been found to contain significantly less strontium.<sup>45</sup> However, supplementation with strontium has not yet been studied as tooth decay prevention.

*Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

**Herbs that may be helpful**

Compounds present in both **green tea** (page 686) and black tea have been shown to inhibit the growth and activity of bacteria associated with tooth decay.<sup>46, 47</sup> Animals given tea compounds in their drinking water develop fewer dental caries than do those drinking plain water.<sup>48, 49, 50</sup> Human volunteers rinsing with an alcohol extract of tea leaves before bed each night for four days had significantly less plaque formation but similar amounts of plaque-causing bacteria compared with those with no treatment.<sup>51</sup> Tea drinking has not yet been tested as a tooth decay preventative in humans.

In a double-blind trial, 1 gram of neem leaf extract in gel twice per day was more effective than chlorhexidine or placebo gel at reducing plaque and bacteria levels in the mouth in 36 Indian adults.<sup>52</sup> A similar trial found neem gel superior to placebo and equally effective as chlorhexidine at reducing plaque and bacteria levels in the mouth.<sup>53</sup> These promising early studies should be followed by studies regarding prevention of cavities and relief from gingivitis or periodontal disease.

*Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

## ULCERATIVE COLITIS

Ulcerative colitis (UC) is a chronic inflammatory disease of the colon, which is relatively common but remains poorly understood.

Diagnosis must be made by a healthcare practitioner—typically a gastroenterologist. **Irritable bowel**

**syndrome** (page 280), a completely unrelated and less serious condition, was sometimes called mucous colitis in the past. As a result, the general term “colitis” is still sometimes used inappropriately to refer to irritable bowel syndrome. It is critical that people who are diagnosed with “colitis” find out whether they have irritable bowel syndrome or UC.

**What are the symptoms of UC?**

UC is characterized by frequent abdominal pain and bloody **diarrhea** (page 163). Other symptoms may include fatigue, weight loss, decreased appetite, and nausea.

**Medical treatments**

The over the counter antidiarrheal drug loperamide (Imodium A-D) may be used in ulcerative colitis patients with **diarrhea** (page 163). Anal irritation and loose stools may sometimes be improved by giving bulk-forming laxative such as methylcellulose (Citrucel) or psyllium (Fiberall, Konsyl, Metamucil, Perdiem).

Diphenoxylate with atropine (Lomotil) is the prescription drug most often used to control diarrhea. Cramps may be treated with anticholinergic drugs, such as L-hyoscymine (Levsin, Levbid) and belladonna (Belladonna Tincture). These drugs must be used with extreme caution to prevent toxic dilation of the colon. Sulfasalazine (Azulfidine) is used in individuals with mild to moderate colitis. Oral corticosteroids, such as prednisone (Deltasone), may be used during acute flare-ups however, long-term corticosteroid therapy may be more harmful than good. Therapy with corticosteroids, such as hydrocortisone enema (Cortenema) is commonly recommended. Mesalamine (Asacol, Pentasa, Rowasa) may be prescribed in some cases, as an enema, orally, or in suppository form. Certain immunosuppressive drugs may also be effective, including azathioprine (Imuran), cyclosporine (Sandimmune), and 6-mercaptopurine (Purinethol). Secondary bacterial **infections** (page 265) are managed with antibiotics.

Other treatment of UC includes avoiding raw fruits and vegetables. Sometimes a milk-free diet is suggested. Toxic colitis, a grave medical emergency complication of UC, is treated intensively in emergency departments with antibiotics, such as tobramycin (Nebcin), amikacin (Amikin), and gentamicin (Garamycin), intravenous fluid replacement, and either corticosteroids or adrenocorticotropic hormone (ACTH). Emergency surgical removal of the colon is sometimes necessary in

the most severe cases. Elective surgery may be recommended for milder cases.

#### CHECKLIST FOR ULCERATIVE COLITIS

Rating	Nutritional Supplements	Herbs
★★☆	Butyrate (enema) <b>Fish oil</b> (page 514) <b>Folic acid</b> (page 520) <b>Probiotics</b> (page 575)	<b>Aloe</b> (page 624) <b>Boswellia</b> (page 644) <b>DHEA</b> (page 503) <b>Psyllium</b> (page 732) Wheat grass (juice)
★★★		<b>Calendula</b> (page 650) <b>Chamomile</b> (page 656) <b>Flaxseed</b> (page 517) <b>Licorice</b> (page 702) <b>Marshmallow</b> (page 708) <b>Myrrh</b> (page 713) <b>St. John's wort</b> (page 747) (oil, taken as an enema) <b>Yarrow</b> (page 763)

#### Dietary changes that may be helpful

Some studies have shown that high sugar intake is associated with an increase in risk for UC.<sup>1,2</sup> Other research has failed to find any association between UC and sugar intake.<sup>3,4</sup> Until more is known, persons with inflammatory bowel diseases, including UC, should consider limiting their intake of sugar.

In two studies, people with a high intake of animal fat, **cholesterol** (page 223), or margarine had a significantly increased risk of UC, compared with people who consumed less of these fats.<sup>5,6</sup> Although these associations do not prove cause-and-effect, reducing one's intake of animal fats and margarine is a means of improving overall health and possibly UC as well.

There is preliminary evidence that people who eat fast food at least twice a week have nearly four times the risk of developing UC than people who do not eat fast food.<sup>7</sup>

More than a half-century ago, several doctors reported that **food allergies** (page 14) play an important role in some cases of UC.<sup>8,9</sup> Since that time, many doctors have observed that avoidance of allergenic foods will often reduce the severity of UC and can sometimes completely control the condition. In other old studies, milk has been reported to trigger UC,<sup>10</sup> and people with UC were found to have antibodies to milk in their blood, a possible sign of allergy.<sup>11</sup> Today the relation-

ship between food allergies and UC remains controversial<sup>12</sup> and is not generally accepted by the conventional medical community. People who wish to explore the possibility that food sensitivities may trigger their symptoms may wish to consult with an appropriate healthcare provider.

In a preliminary study, 39 patients with mild to moderate ulcerative colitis experienced significant improvement after receiving 30 grams (about 1 oz) per day of a germinated barley product for four weeks.<sup>13</sup> Controlled trials are needed to confirm this report.

#### Lifestyle changes that may be helpful

For unknown reasons, smokers have a lower risk of UC. The nicotine patch has actually been used to induce remissions in people with UC,<sup>14</sup> although this treatment has been ineffective in preventing relapses.<sup>15</sup> On the other hand, **Crohn's disease** (page 141), which is in many ways similar to UC, is made *worse* by smoking.<sup>16</sup> Despite the possible protective effect of smoking in people with UC, a strong case can be made that risks of smoking outweigh the benefits; even the use of nicotine patches carries its own side effects and remains experimental.

#### Nutritional supplements that may be helpful

UC is linked to an increased risk of **colon cancer** (page 000). Studies have found that people with UC who take **folic acid** (page 520) supplements or who have high blood levels of folic acid have a reduced risk of colon cancer compared with people who have UC and do not take folic acid supplements.<sup>17, 18, 19</sup> Although these associations do not prove that folic acid was responsible for the reduction in risk, this vitamin has been shown to prevent experimentally induced colon cancer in animals.<sup>20</sup> Moreover, low blood folic acid levels have been found in more than half of all people with UC.<sup>21</sup> People with UC who are taking the drug sulfasalazine, which inhibits the absorption of folic acid,<sup>22</sup> are at a particularly high risk of developing folic acid deficiency. Folic acid supplementation may therefore be important for many people with UC. Since taking folic acid may mask a **vitamin B<sub>12</sub>** (page 601) deficiency, however, people with UC who wish to take folic acid over the long term should have their vitamin B<sub>12</sub> status assessed by a physician.

Alcohol consumption is known to promote folic acid deficiency and has also been linked to an increased risk of colon cancer.<sup>23</sup> People with UC should, therefore, keep alcohol intake to a minimum.

Preliminary<sup>24</sup> and double-blind trials<sup>25, 26, 27</sup> have found that **fish oil** (page 514) supplementation reduces inflammation, decreases the need for anti-inflammatory drugs, and promotes normal weight gain in people with UC. However, fish oil has not always been effective in clinical trials for UC.<sup>28</sup> Amounts used in successful clinical trials provided 3.2 grams of EPA and 2.2 grams of **DHA** (page 509) per day—the two important fatty acids found in fish oil.

A fatty acid called butyrate, which is synthesized by intestinal bacteria, serves as fuel for the cells that line the small intestine. Administration of butyrate by enema has produced marked improvement in people with UC in most,<sup>29, 30, 31, 32, 33, 34</sup> but not all,<sup>35</sup> preliminary trials. Butyrate taken by mouth is not likely to be beneficial, as sufficient quantities do not reach the colon by this route. Although butyrate enemas are not widely available, they can be obtained by prescription through a compounding pharmacy, which prepares customized prescription medications to meet individual patient needs.

In a preliminary trial, 6 of 13 people with ulcerative colitis went into remission after taking 200 mg per day of **DHEA** (page 503) for eight weeks.<sup>36</sup> This large amount of DHEA has the potential to cause adverse side effects and should only be used under the supervision of a doctor.

In preliminary<sup>37</sup> and double-blind<sup>38</sup> trials, a **probiotic** (page 575) supplement (in this case, a non-disease-causing strain of *Escherichia coli*) was effective at maintaining remission in people with UC. In a double-blind trial, a combination probiotic supplement containing Lactobacilli, Bifidobacteria, and a beneficial strain of Streptococcus has been shown to prevent pouchitis, a common complication of surgery for UC.<sup>39</sup> People with chronic relapsing pouchitis received either 3 grams per day of the supplement or placebo for nine months. Eighty-five percent of those who took the supplement had no further episodes of pouchitis during the nine-month trial, whereas 100% of those receiving placebo had relapses within four months. Preliminary evidence suggests that combination probiotic supplements may be effective at preventing UC relapses as well.<sup>40</sup>

In a preliminary trial, people with UC significantly improved on a sugar-free, low-allergen diet with additional nutritional supplementation that included a **multivitamin-mineral** (page 559) supplement (2–6 tablets per day); a **fish oil** (page 514) supplement (400 mg per day); **borage oil** (page 475) (400 mg per day);

**flaxseed oil** (page 517) (400 mg per day); and a probiotic formula containing *Lactobacillus acidophilus* (page 575) and other species of beneficial bacteria.<sup>41</sup> Some participants received slight variations of this regimen. Since so many different supplements were given and since the trial was not controlled, it is not possible to say which, if any, of the nutrients was responsible for the improvement observed by the researchers.

#### *Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

#### **Herbs that may be helpful**

A small clinical study found that people with UC taking 550 mg of **boswellia** (page 644) gum resin three times daily for six weeks had similar improvement in symptoms and the severity of their disease as people with UC taking the drug sulfasalazine.<sup>42</sup> Overall, 82% of patients receiving boswellia, along with 75% of patients taking sulfasalazine, went into remission.

In a preliminary trial, people with UC remained in remission just as long when they took 20 grams of ground **psyllium** (page 732) seeds twice daily with water as when they took the drug mesalamine.<sup>43</sup> The combination of the two was slightly more effective than either alone. Controlled trials are now needed to confirm a therapeutic effect of psyllium for UC.

In a controlled trial, supplementation with wheat grass juice for one month resulted in clinical improvement in 78% of people with ulcerative colitis, compared with 30% of those receiving a placebo.<sup>44</sup> The amount of wheat grass used was 20 ml per day initially; this was increased by 20 ml per day to a maximum of 100 ml per day (approximately 3.5 ounces).

German doctors practicing herbal medicine often recommend **chamomile** (page 656) for people with colitis.<sup>45</sup> A cup of strong tea drunk three times per day is standard, along with enemas using the tea when it reaches body temperature.

Enemas of oil of **St. John's wort** (page 747) may also be beneficial.<sup>46</sup> Consult with a doctor before using St. John's wort oil enemas.

**Aloe vera** (page 624) juice has anti-inflammatory activity and been used by some doctors for people with UC. In a double-blind study of people with mildly to moderately active ulcerative colitis, supplementation with aloe resulted in a complete remission or an improvement in symptoms in 47% of cases, compared with 14% of those given a placebo (a statistically signif-

icant difference).<sup>47</sup> No significant side effects were seen. The amount of aloe used was 100 ml (approximately 3.5 ounces) twice a day for four weeks. Other traditional anti-inflammatory and soothing herbs, including **calendula** (page 650), **flaxseed** (page 517), **licorice** (page 702), **marshmallow** (page 708), **myrrh** (page 713), and **yarrow** (page 763). Many of these herbs are most effective, according to clinical experience, if taken internally as well as in enema form.<sup>48</sup> Enemas should be avoided during acute flare-ups but are useful for mild and chronic inflammation. It is best to consult with a doctor experienced with botanical medicine to learn more about herbal enemas before using them. More research needs to be done to determine the effectiveness of these herbs.

*Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

## URINARY TRACT INFECTION

### What do I need to know?

Self-care for urinary tract infection can be approached in a number of ways—but it can be hard to know just where to start. To make it easier, our doctors recommend trying these simple steps first:

*If you have a UTI, see a doctor*

Existing infections may require treatment with antibiotics

*Check out cranberry*

To treat and to prevent recurrences, drink 4 to 10 ounces a day of cranberry juice or take 400 mg of powdered cranberry concentrate twice a day

*Try proteolytic enzymes*

To enhance antibiotic effectiveness, take 400 mg a day of enzymes such as bromelain and trypsin

*Avoid allergic foods*

Work with a knowledgeable health practitioner to find out if you have allergies to foods that increase your susceptibility to urinary tract infections

*Aim for a strong immune system with a multivitamin-mineral supplement*

Take one daily to avoid deficiencies and better resist infections

### About UTIs

Urinary tract infections (UTIs) are **infections** (page 265) of the kidney, bladder, and urethra.

UTIs are generally triggered by bacteria and are more common when there is partial blockage of the urinary tract. In some people, UTIs tend to recur.

### CHECKLIST FOR URINARY TRACT INFECTION (UTI)

Rating	Nutritional Supplements	Herbs
★☆☆	<b>Bromelain</b> (page 481)	<b>Cranberry</b> (page 664)
★☆☆	<b>D-mannose</b> (page 503) <b>Multivitamin-mineral</b> (page 559) <b>Vitamin A</b> (page 595) <b>Vitamin C</b> (page 604)	Asparagus Birch <b>Blueberry</b> (page 641) <b>Buchu</b> (page 645) Couch grass Goldenrod <b>Goldenseal</b> (page 683) <b>Horseradish</b> (page 693) <b>Horsetail</b> (page 693) Java tea <b>Juniper</b> (page 698) Lovage <b>Nettle</b> (page 714) <b>Oregon grape</b> (page 721) Parsley <b>Plantain</b> (page 729) <b>Sassafras</b> (page 742) Spiny restharrow <b>Uva ursi</b> (page 755)

### What are the symptoms of UTIs?

Symptoms of a UTI usually begin suddenly and include frequent urination that is irritating or burning, a persistent urge to urinate even after the bladder has been emptied, and cramping or pressure in the lower abdomen. The urine often has a strong or unusual smell and may appear cloudy. In more serious **infections** (page 265), fever, chills, **pain** (page 338) in the back below the ribs, nausea, vomiting, and **diarrhea** (page 163) may also be present.

### Medical treatments

Over the counter products containing phenazopyridine (Azo-Standard, Prodium) may be used to relieve pain, burning, and urgency, but they do not treat the infection.

Oral antibiotics are typically used to treat uncomplicated **infections** (page 265); the most commonly prescribed are the combination drug trimethoprim/sulfamethoxazole (Bactrim, Septra) and the fluoroquinolones, such as levofloxacin (Levaquin), ciprofloxacin (Cipro), and ofloxacin (Floxin). One of the third-generation cephalosporins, cefixime (Suprax) and the tetracyclinedoxycycline (Vibramycin) may be used as well.

Intravenous antibiotics, such as the aminoglycosides gentamicin (Garamycin) and tobramycin (Nebicin, To-brex), may be used for more serious infections.

#### Dietary changes that may be helpful

When healthy volunteers consumed a large amount (100 grams) of refined sugar, the ability of their white blood cells to destroy bacteria was impaired for at least five hours.<sup>1</sup> Consumption of excessive amounts of alcohol has also been shown to suppress **immune function** (page 255).<sup>2</sup> Reduced intake of dietary fat has been shown to stimulate immunity.<sup>3</sup> For these reasons, many doctors recommend a reduced intake of sugar, alcohol, and fat during an acute **infection** (page 265) and for prevention of recurrences.

People who have recurrent or chronic infections should discuss the possible role of **allergies** (page 14) with a doctor, since chronic infections have been linked to allergies in many reports.<sup>4, 5, 6, 7</sup> Identifying and eliminating foods that trigger problems may help reduce the number of infections.

#### Nutritional supplements that may be helpful

The proteolytic **enzymes** (page 506), **bromelain** (page 481) (from pineapple) and trypsin may enhance the effectiveness of antibiotics in people with a UTI. In a double-blind trial, people with UTIs received antibiotics plus either bromelain/trypsin in combination (400 mg per day for two days) or a placebo. One hundred percent of those who received the enzymes had a resolution of their **infection** (page 265), compared with only 46% of those given the placebo.<sup>8</sup> This study used enteric-coated tablets. Enteric-coating prevents stomach acid from partially destroying the bromelain. Most commercially available bromelain products today are not enteric-coated, and it is not known if non-enteric coated preparations would be as effective.

Some bacteria that typically cause urinary tract infections can attach themselves to the lining of the urinary tract by binding to molecules of **mannose** (page 503) that naturally occur there.<sup>9</sup> Theoretically, if enough D-mannose is present in the urine, it would bind to the

bacteria and prevent them from attaching to the urinary tract lining.<sup>10</sup> One animal study has demonstrated this protective effect,<sup>11</sup> but whether it would occur in humans is unknown, and no human research has investigated the effectiveness of oral D-mannose for the prevention or treatment of urinary tract infections.

Many doctors recommend 5,000 mg or more of **vitamin C** (page 604) per day for an acute UTI, as well as long-term supplementation for people who are prone to recurrent UTIs. Although no controlled clinical trials have demonstrated the effectiveness of vitamin C for this purpose, vitamin C has been shown to inhibit the growth of *E. coli*, the most common bacterial cause of UTIs.<sup>12</sup> In addition, supplementation with 4,000 mg or more of vitamin C per day, results in a slight increase in the acidity of the urine,<sup>13</sup> creating an “unfriendly” environment for some infection-causing bacteria.

**Vitamin A** (page 595) deficiency increases the risk of many infections. Although much of the promising research with vitamin A supplements and infections has focused on measles,<sup>14</sup> vitamin A is also thought to be helpful in other infections. Some doctors recommend that people with urinary tract infections take vitamin A. A typical amount recommended to correct a deficiency is 10,000 to 25,000 IU per day.

Since the **immune system** (page 255) requires many nutrients in order to function properly, many people take a **multivitamin-mineral** (page 559) supplement for “insurance.” In one double-blind trial, healthy elderly people who used such a supplement for one year showed improvements in immune function, as well as a significant reduction in the total number of infections (including non-urinary-tract infections).<sup>15</sup>

#### Are there any side effects or interactions?

Refer to the individual supplement for information about any side effects or interactions.

#### Herbs that may be helpful

Modern research has suggested that **cranberry** (page 664) may prevent urinary tract infections. In a double-blind trial, elderly women who drank 10 ounces (300 ml) of cranberry juice per day had a decrease in the amount of bacteria in their urine.<sup>16</sup> In another study, elderly residents of a nursing home consumed either four ounces (120 ml) of cranberry juice or six capsules containing concentrated cranberry daily for 13 months. During that time, the number of UTIs decreased by 25%.<sup>17</sup> A small preliminary trial found that supplementation with encapsulated cranberry concentrate (400

mg twice per day for three months) significantly reduced the recurrence of UTIs in women (aged 18–45) with a history of recurrent infections.<sup>18</sup>

Research has suggested cranberry may be effective against UTIs because it prevents *E. coli*, the bacteria that causes most urinary tract infections (page 265), from attaching to the walls of the bladder.<sup>19</sup> Cranberry is not, however, a substitute for antibiotics in the treatment of acute UTIs. Moreover, in children whose UTIs are due to “neurogenic bladder” (a condition caused by spinal cord injury or myelomeningocele), cranberry juice supplementation did not reduce the rate of infection.<sup>20</sup> Drinking 10–16 ounces (300–500 ml) of unsweetened or lightly sweetened cranberry juice is recommended by many doctors for prevention, and as part of the treatment of UTIs. Alternatively, 400 mg of concentrated cranberry extracts twice per day can be used.

**Blueberry** (page 641) contains similar constituents as cranberry, and might also prevent bacteria from attaching to the lining of the urinary bladder.<sup>21</sup> However, studies have not yet been done to determine if blueberry can help prevent bladder infections.

Asparagus (*Asparagus officinalis*), birch (*Betula spp.*), couch grass (*Agropyron repens*), goldenrod (*Solidago virgaurea*), **horsetail** (page 693), Java tea (*Orthosiphon stamineus*), lovage (*Levisticum officinale*), parsley (*Petroselinum crispum*), spiny restharrow (*Ononis spinosa*), and **nettle** (page 714) are approved in Germany as part of the therapy of people with UTIs. These herbs appear to work by increasing urinary volume and supposedly helping to flush bacteria out of the urinary tract.<sup>22</sup> **Juniper** (page 698) is used in a similar fashion by many doctors. Generally, these plants are taken as tea.

**Buchu** (page 645) leaf preparations have a history of use in traditional herbal medicine as a urinary tract disinfectant and diuretic.<sup>23</sup> However, the German Commission E monograph on buchu concludes that insufficient evidence supports the modern use of buchu for the treatment of UTIs or inflammation.<sup>24</sup>

The volatile oil of **horseradish** (page 693) has been shown to kill bacteria that can cause urinary tract infections.<sup>25</sup> The concentration that is required to kill these bacteria can be attained in human urine after oral ingestion of the oil. One early study found that horseradish extract may help people with urinary tract infections.<sup>26</sup> Further studies are necessary to confirm the safety and effectiveness of horseradish in treating urinary tract infections.

**Goldenseal** (page 683) is reputed to help treat many types of **infections** (page 265). It contains berberine, an

alkaloid that may prevent UTIs by inhibiting bacteria from adhering to the wall of the urinary bladder.<sup>27</sup> Goldenseal and other plants containing berberine (such as **Oregon grape** [page 721]) may help in the treatment of UTIs. These herbs have not, however, been studied for the treatment of UTIs in humans.

Because of the anti-inflammatory effects of **plantain** (page 729), it may be beneficial in some people with UTIs. However, human trials have not been done to confirm this possibility or to confirm the traditional belief that plantain is diuretic.<sup>28</sup>

An extract of **uva ursi** (page 755) is used in Europe and in traditional herbal medicine in North America, as a treatment for UTI.<sup>29</sup> This herb is approved in Germany for treatment of bladder infections.<sup>30</sup> The active constituent in uva ursi is arbutin. In the alkaline environment of the urine, arbutin is converted into another chemical, called hydroquinone, which kills bacteria. A generally useful amount of uva ursi tincture is 3–5 ml three times per day. Otherwise, 100–250 mg of arbutin in herbal extract capsules or tablets three times per day can be used. Uva ursi should only be used to treat a UTI under the close supervision of a physician.

#### *Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

#### **Holistic approaches that may be helpful**

Acupuncture might be of some benefit for women with recurrent UTIs. A controlled study compared acupuncture to sham (“fake”) acupuncture or no treatment in a group of women with recurrent UTIs. After six months, the women receiving real acupuncture had half as many UTI episodes as the sham group and only one-third as many as the untreated group, a significant difference.<sup>31</sup>

## VAGINITIS

Vaginitis is inflammation of the vagina.

Vaginitis is responsible for an estimated 10% of all visits by women to their healthcare practitioners. The three general causes of vaginitis are hormonal imbalance, irritation, and infection. Hormone-related vaginitis includes the atrophic vaginitis generally found in **postmenopausal** (page 311) or **postpartum** (page 363) women and, occasionally, in young girls before puberty. Irritant vaginitis can result from **allergies**

(page 14) or irritating substances. Infectious vaginitis is most common in reproductive-age women and is generally caused by one of three types of infections: bacterial vaginosis (BV), candidiasis (**yeast infection** [page 454]), or trichomoniasis. A healthcare professional should be consulted for the diagnosis and treatment of any vaginal infection.

Although it is a type of vaginitis, yeast infection is not discussed on this page. For specific information on yeast infections (i.e., vaginitis caused by *Candida albicans*), see the **yeast infections** (page 454) article.

CHECKLIST FOR VAGINITIS		
Rating	Nutritional Supplements	Herbs
★★★	<b>Lactobacillus acidophilus</b> (page 575)	
★☆☆	<b>Soy</b> (page 587) <b>Vitamin A</b> (page 595) <b>Vitamin E</b> (page 609)	<b>Barberry</b> (page 632) <b>Echinacea</b> (page 669) <b>Goldenseal</b> (page 683) <b>Tea tree</b> (page 751) Neem

### What are the symptoms of vaginitis?

Hormone-related vaginitis is marked by dryness, irritation, thinning of the vaginal mucous membranes and painful intercourse. Irritant vaginitis is characterized by itching and soreness. Infectious vaginitis also itches and typically includes vaginal discharge that varies in color, consistency, and odor, depending upon the infectious organism. Discharge may range from scant to thick and white and may or may not be accompanied by a strong odor. Symptoms are often worse immediately after intercourse or the menstrual period.

### Medical treatments

Over the counter drugs are available to treat vaginitis caused by candida. They include clotrimazole (Gyne-Lotrimin, Mycelex), miconazole (Monistat), and butoconazole (Femstat). Irritant vaginitis can be treated either by removal of the offending irritant or with an antihistamine agent, such as diphenhydramine (Benadryl).

Prescription drug therapy varies with the cause of the vaginitis. Hormone-related vaginitis is commonly treated with estrogen replacement therapy, including conjugated estrogens (Premarin), estradiol (Estrace),

and ethynodiol dienoate (Estinyl). Bacterial vaginosis and trichomoniasis are each commonly treated with metronidazole (Flagyl).

### Dietary changes that may be helpful

**Food allergies** (page 14) are believed to be a contributory factor in some cases of recurrent irritant vaginitis.

In a controlled trial, women with recurrent BV or vaginal candidiasis ate 5 ounces (150 grams) of yogurt containing live *Lactobacillus acidophilus* (page 575) daily.<sup>1</sup> They had more than a 50% reduction in recurrences, while women who consumed pasteurized yogurt that did not contain the bacteria had only a slight reduction.

In another study, women who ingested 45 grams of soy flour per day showed an improvement in the estrogen effect on their vaginal tissue.<sup>2</sup> That observation suggests that supplementing with soy may be helpful for preventing or reversing atrophic vaginitis.

### Lifestyle changes that may be helpful

For irritant vaginitis, minimizing friction and reducing exposure to perfumes, chemicals, irritating lubricants, and spermicides can be beneficial.

### Nutritional supplements that may be helpful

*Lactobacillus acidophilus* (page 575) is a strain of friendly bacteria that is an integral part of normal vaginal flora. Lactobacilli help maintain the vaginal microflora by preventing overgrowth of unfriendly bacteria and Candida. Lactobacilli produce lactic acid, which acts like a natural antibiotic. These friendly bacteria also compete with other organisms for the utilization of glucose. The production of lactic acid and hydrogen peroxide by lactobacilli also helps to maintain the acidic pH needed for healthy vaginal flora to thrive. Most of the research has used yogurt containing live cultures of *Lactobacillus acidophilus* or the topical application of such yogurt or *Lactobacillus acidophilus* into the vagina. The effective amount of acidophilus depends on the strain used, as well as on the concentration of viable organisms.

Vaginal application of a proprietary *Lactobacillus acidophilus* preparation may help nonspecific vaginitis. In one trial, 80% of women with nonspecific vaginitis who used the preparation were either cured or experienced marked improvement in symptoms.<sup>3</sup> In another trial, women who were predisposed to vaginal Candida **infection** (page 265) because they were **HIV-positive** (page 234) received either *Lactobacillus acidophilus* vaginal

suppositories, the antifungal drug, clotrimazole (e.g., Gyne-Lotrimin), or placebo weekly for 21 months.<sup>4</sup> Compared to those receiving placebo, women receiving *Lactobacillus acidophilus* suppositories had only half the risk of experiencing an episode of *Candida* vaginitis—a result almost as good as that achieved with clotrimazole. In a preliminary trial, women with vaginal *Trichomonas* infection received vaginal *Lactobacillus acidophilus* suppositories for one year.<sup>5</sup> Over 90% of them were reported to be cured of their clinical symptoms in that time.

Some doctors recommend **vitamin E** (page 609) (taken orally, topically, or vaginally) for certain types of vaginitis. Vitamin E as a suppository in the vagina or vitamin E oil can be used once or twice per day for 3 to 14 days to soothe the mucous membranes of the vagina and vulva. Some doctors recommend vaginal administration of **vitamin A** (page 595) to improve the integrity of the vaginal tissue and to enhance the function of local immune cells. Vitamin A can be administered vaginally by inserting a vitamin A capsule or using a prepared vitamin A suppository. Vitamin A used this way can be irritating to local tissue, so it should not be used more than once per day for up to seven consecutive days.

#### *Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

#### **Herbs that may be helpful**

In a double-blind, placebo-controlled trial, a cream containing neem seed extract, saponins of *Sapindus mukerossi* (reetha), and quinine hydrochloride (5 ml applied vaginally once at bedtime) eliminated all symptoms in 10 of 14 women with chlamydia compared with none of 4 women given placebo cream.<sup>6</sup> Neither cream was effective in women with trichomoniasis or candidal vaginitis.

Topically applied **tea tree** (page 751) oil has been studied and used successfully as a topical treatment for *Trichomonas*, *Candida albicans*, and other vaginal **infections** (page 265).<sup>7</sup> Tea tree oil must be diluted when used as a vaginal douche, and should only be used for this purpose under the supervision of a healthcare practitioner. Some physicians suggest using tea tree oil by mixing the full-strength oil with **vitamin E** (page 609) oil in the proportion of 1/3 tea tree oil to 2/3 vitamin E oil. A tampon is saturated with this mixture or the mixture is put in a capsule to be inserted in the vagina each day for a maximum of six weeks.

Teas of **goldenseal** (page 683), **barberry** (page 632), and **echinacea** (page 669) are also sometimes used to treat infectious vaginitis. Although all three plants are known to be antibacterial in the test tube, the effectiveness of these herbs against vaginal infections has not been tested in humans. The usual approach is to douche with one of these teas twice each day, using 1–2 tablespoons (15–30 grams) of herb per pint of water. One to two pints (500–1,000 ml) are usually enough for each douching session. Echinacea is also known to improve **immune function** (page 255) in humans.<sup>8</sup> In order to increase resistance against infection, many doctors recommend oral use of the tincture or alcohol-preserved fresh juice of echinacea (1 teaspoon (5 ml) three or more times per day)—during all types of infection—to improve resistance.

#### *Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

## VARICOSE VEINS

Varicose veins are twisted, enlarged veins close to the surface. They can occur almost anywhere but most commonly occur in the esophagus and the legs.

Veins, which return blood to the heart, contain valves that keep blood from flowing backward as a result of gravity. When these valves become weak, blood pools in the veins of the legs and causes them to bulge. These enlarged vessels are called varicose veins. Standing and sitting for long periods of time, lack of exercise, **obesity** (page 446), and **pregnancy** (page 363) all tend to promote the formation of varicose veins. Sometimes varicose veins are painful, but elevating the affected leg usually brings significant relief.

#### CHECKLIST FOR VARICOSE VEINS

Rating	Nutritional Supplements	Herbs
★☆☆	<b>Flavonoids</b> (page 516) (hydroxyethylrutosides) <b>Proanthocyanidins</b> (page 574)	<b>Butcher's broom</b> (page 649) <b>Gotu kola</b> (page 684) <b>Horse chestnut</b> (page 692) <b>Witch hazel</b> (page 760)

### What are the symptoms of varicose veins?

Symptoms of varicose veins may include a dull pain, itch, or heavy sensation in the legs. The sensation is worse after prolonged standing and better when the legs are elevated. Varicose veins typically appear on the legs as dilated, tortuous veins close to the surface of the skin, and may look blue. Advanced varicose veins may cause ankle and leg swelling or **skin ulcers** (page 409).

### Medical treatments

Other treatment is to elevate the legs frequently, avoid prolonged standing or sitting, and wear compression stockings with supportive shoes. Other treatments include surgery to remove the vein, laser therapy, and sclerotherapy, which involves the injection of a chemical solution into the vein to cause it to close. Any skin ulcers that develop are treated with compressive bandages that contain antibiotic solutions.

### Lifestyle changes that may be helpful

Keeping the legs elevated relieves pain. People with varicose veins should avoid sitting or standing for prolonged periods of time and should walk regularly.

### Nutritional supplements that may be helpful

A controlled clinical trial found that oral supplementation with hydroxyethylrutosides (HR), a type of **flavonoid** (page 516) that is derived from rutin, improved varicose veins in a group of **pregnant** (page 363) women.<sup>1</sup> Further research is needed to confirm the benefits observed in this preliminary trial. A typical amount of HR is 1000 mg per day.

A small, preliminary trial found that supplementation with 150 mg of **proanthocyanidins** (page 574) per day improved the function of leg veins after a single application in people with widespread varicose veins.<sup>2</sup> Double-blind trials are needed to determine whether extended use of proanthocyanidins can substantially improve this condition.

### Are there any side effects or interactions?

Refer to the individual supplement for information about any side effects or interactions.

### Herbs that may be helpful

Although **witch hazel** (page 760) is known primarily for treating **hemorrhoids** (page 219), it may also be useful for varicose veins.<sup>3</sup> Topical use of witch hazel to treat venous conditions is approved by the German Commission E, authorities on herbal medicine.<sup>4</sup> Appli-

cation of a witch hazel ointment three or more times per day for two or more weeks is necessary before results can be expected.

**Horse chestnut** (page 692) seed extract can be taken orally or used as an external application for disorders of venous circulation, including varicose veins.<sup>5</sup> Preliminary studies in humans have shown that 300 mg three times per day of a standardized extract of horse chestnut seed reduced the formation of enzymes thought to cause varicose veins.<sup>6</sup> Topical gel or creams containing 2% aescin can be applied topically three or four times per day to the affected limb(s).

Oral supplementation with **butcher's broom** (page 649)<sup>7</sup> or **gotu kola** (page 684)<sup>8</sup> may also be helpful for varicose veins.

### Are there any side effects or interactions?

Refer to the individual herb for information about any side effects or interactions.

## VERTIGO

Vertigo is a sensation of irregular or whirling motion, either of oneself or of external objects.

The word is sometimes incorrectly used as a general term to describe dizziness. The most common form of vertigo is benign positional paroxysmal vertigo (BPPV), in which brief attacks are brought on by certain changes in head position.<sup>1</sup> BPPV may be due to a previous head injury, viral **infection** (page 265), and certain drug therapies, although in about half the cases the cause is unknown.<sup>2, 3</sup> BPPV tends to resolve without treatment within weeks to months, but may persist for years in some cases.<sup>4, 5</sup>

People experiencing vertigo should have a complete medical evaluation to determine the cause. Common causes of non-BPPV vertigo include conditions in which there is decreased blood flow to certain areas of the brain, **Ménière's disease** (page 308), and infection of the inner ear.<sup>6, 7</sup> Vertigo may also be a symptom of numerous other conditions,<sup>8, 9, 10</sup> including **sinusitis** (page 407), **panic attacks** (page 30), **migraine headaches** (page 316), and problems with metabolism,<sup>11, 12</sup> such as **hypothyroidism** (page 252), **high blood triglycerides** (page 235), **diabetes** (page 152), and **hypoglycemia** (page 251).

### What are the symptoms of vertigo?

People with vertigo may have sudden sensations of spinning or whirling motion that may be accompanied

by lightheadedness and loss of balance, and less often by sweating, fatigue, nausea, and vomiting.<sup>13, 14</sup>

#### CHECKLIST FOR VERTIGO

Rating	Nutritional Supplements	Herbs
★★☆	<b>Vinpocetine</b> (page 594) <b>Vitamin B<sub>6</sub></b> (page 600)	<b>Ginger</b> (page 680) <b>Ginkgo biloba</b> (page 681)

#### Medical treatments

Over the counter medication such as dimenhydrinate (Dramamine), meclizine (Bonine), and cyclizine (Marezine) may be helpful.

Prescription medications include anticholinergic drugs, such as scopolamine (Transderm Scop), prochlorperazine (Compazine), and meclizine (Antivert), as well as sedatives, including diazepam (Valium), lorazepam (Ativan), and alprazolam (Xanax).

Healthcare practitioners recommend getting fresh air, lying down, closing the eyes, and alcohol avoidance. People frequently affected by severe, disabling vertigo may require a surgical treatment, such as vestibular neurectomy or labyrinthectomy. These procedures involve surgical removal of either the nerves or labyrinthine structures that control balance and position senses.

#### Dietary changes that may be helpful

In preliminary studies, vertigo associated with **high triglycerides** (page 235), **diabetes mellitus** (page 152), and **hypoglycemia** (page 251) responded to dietary management of the underlying disorder.<sup>15, 16</sup> In a preliminary study of people with **migraine headaches** (page 316), most of whom (83%) also experienced vertigo, a multifaceted approach including dietary changes was investigated. Dietary changes involved the elimination of foods and food additives suspected of causing migraine attacks. This approach resulted in complete or substantial improvement of symptoms in a significant number of participants.<sup>17</sup> No other research has investigated the effects of diet on vertigo.

#### Lifestyle changes that may be helpful

Head positions that bring on sudden, acute attacks of vertigo, particularly bending the neck back while looking up, should be avoided. In one report, for example, the head position used in salons for shampooing hair was associated with the onset of vertigo.<sup>18</sup> According to

one authority,<sup>19</sup> certain chronic or repetitive body positions may produce painful nodules, called trigger points, in the muscles of the head and neck, which can lead to dizziness and possibly vertigo. These positions include forward bending of the neck as when sleeping on two pillows, backward neck bending as when painting a ceiling, and turning the neck to one side as in some reading positions.<sup>20</sup> A healthcare practitioner knowledgeable in postural education can give advice on avoiding such positions. Trigger point therapy is discussed below in "Other integrative approaches that may be helpful."

#### Nutritional supplements that may be helpful

A preliminary trial showed that 15 mg per day of **vinpocetine** (page 594) had a moderate or greater effect on reducing the signs and symptoms of vertigo in 77% of patients with this condition.<sup>21</sup> Other preliminary reports exist describing benefits of vinpocetine for vertigo and other symptoms of inner ear disorders,<sup>22</sup> but controlled research is needed to evaluate these claims.

Two preliminary human studies reported that **vitamin B<sub>6</sub>** (page 600) supplementation reduced symptoms of vertigo produced with drugs in a laboratory setting.<sup>23</sup> Vitamin B<sub>6</sub> supplementation has not been studied in BPPV or other forms of vertigo and may not share the same causative mechanism as experimentally induced vertigo.

#### Are there any side effects or interactions?

Refer to the individual supplement for information about any side effects or interactions.

#### Herbs that may be helpful

In a preliminary clinical trial, a standardized extract of **Ginkgo biloba** (page 681) (GBE) significantly reduced symptoms of vertigo in a group of elderly people with mild cognitive impairment.<sup>24</sup> Participants were given 40 mg three times per day for one year. GBE has also been reported to significantly reduce vertigo of unknown cause in preliminary<sup>25</sup> and double-blind<sup>26</sup> trials. The amounts given were 120 mg and 160 mg per day, respectively, for three months.

One gram of powdered **ginger** (page 680) (*Zingiber officinale*) root in a single application has been reported to significantly reduce symptoms of artificially induced vertigo in one double-blind trial.<sup>27</sup> In a double-blind trial, 1 gram of powdered ginger root was found to have very little effect in reducing vertigo related to **seasickness** (page 322).<sup>28</sup>

*Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

**Holistic approaches that may be helpful**

**Other integrative approaches that may be helpful:** Numerous preliminary reports suggest certain “vestibular rehabilitation” exercises may help some cases of vertigo.<sup>29, 30, 31, 32, 33, 34</sup> These exercises were also found to be effective in relieving vertigo in two controlled studies,<sup>35</sup> including one on BPPV.<sup>36</sup> While vestibular rehabilitation exercises may be done at home, initial guidance by a qualified practitioner is necessary.

BPPV appears to be caused by an accumulation of free-floating cell fragments in the fluid of the inner ear.<sup>37, 38</sup> Certain manipulation therapy maneuvers, referred to as particle repositioning maneuvers (PRMs), are intended to relocate this debris to a harmless location,<sup>39, 40, 41</sup> in order to improve symptoms. Both preliminary<sup>42, 43, 44, 45, 46</sup> and controlled<sup>47, 48, 49</sup> trials achieved significant improvement in, or elimination of, BPPV using these maneuvers. Most studies report that over 90% of people with BPPV treated one or two times with PRM respond to this treatment, although up to 45% may develop BPPV again within a few years, requiring further treatments.<sup>50, 51, 52</sup>

Research indicates some cases of vertigo are related to spinal disorders affecting the head and neck.<sup>53, 54, 55, 56, 57, 58, 59</sup> Preliminary studies report that certain treatments, such as spinal manipulation,<sup>60, 61, 62, 63</sup> physical therapy,<sup>64</sup> and combined approaches including manipulation and specific exercise programs,<sup>65, 66</sup> result in significant improvement of vertigo symptoms.

Trigger points are thought by most,<sup>67, 68, 69</sup> though not all,<sup>70</sup> authorities to potentially cause pain and abnormal function in other parts of the body. Trigger points appear to develop as the result of injury, poor posture, structural abnormalities of the leg or pelvis, emotional tension, and other body stressors.<sup>71, 72</sup> Also known as myofascial pain dysfunction (MPD), this condition, when it affects certain muscles of the head and neck, has been associated with vertigo in preliminary research.<sup>73, 74, 75</sup> Musculoskeletal healthcare specialists and other practitioners can often treat MPD with a variety of natural therapies, including deep pressure massage,<sup>76, 77, 78, 79, 80</sup> transcutaneous electrical nerve stimulation (TENS),<sup>81, 82</sup> and other approaches,<sup>83</sup> but no controlled studies have investigated the effectiveness of these treatments specifically for vertigo.

In a preliminary study of people with migraine

headaches, most of whom (83%) also experienced vertigo, a combined and individualized approach using dietary changes, medication, physical therapy, lifestyle changes, and acupuncture resulted in complete or substantial improvement of symptoms in a significant number of participants.<sup>84</sup> In addition, a large number of case studies presented in two preliminary reports suggest acupuncture may help to reduce symptoms of vertigo.<sup>85, 86</sup> These preliminary studies have yet to be confirmed by controlled clinical trials.

## VITILIGO

Vitiligo is a type of skin discoloration characterized by progressively widening areas of depigmented (very white) skin.

The depigmentation that occurs with this condition is associated with the local destruction of melanocytes, the cells that produce the pigment that darkens the skin, called melanin. Vitiligo affects 1–4% of the world’s population.<sup>1</sup>

### CHECKLIST FOR VITILIGO

Rating	Nutritional Supplements	Herbs
★☆☆	<b>L-phenylalanine</b> (page 568)	<b>Ginkgo biloba</b> (page 681) Khella <b>Picrorhiza</b> (page 728)
★☆☆	<b>Betaine HCl</b> (page 473) <b>Folic acid</b> (page 520) <b>PABA</b> (page 567) <b>Vitamin B-complex</b> (page 603) <b>Vitamin B<sub>12</sub></b> (page 601) <b>Vitamin C</b> (page 604) <b>Vitamin D</b> (page 607) (topical calcipotriol only)	

**What are the symptoms of vitiligo?**

Symptoms of vitiligo include decreased or absent pigmentation in localized or diffuse areas of the skin. Hair in these areas is typically white, and the skin tends to sunburn more easily.

**Medical treatments**

Prescription topical corticosteroids, such as triamcinolone (Kenalog, Aristocort), betamethasone (Valisone,

Diprosone), and fluocinonide (Lidex), might help in some situations. Oral and topical psoralens, including methoxsalen (Oxsoralen) and trioxsalen (Trisoralen) with ultraviolet A irradiation (PUVA), are occasionally used.

Other treatment includes cosmetic creams and tanning solutions. Treatment may also involve the management of any underlying medical condition, such as Vogt-Koyanagi-Harada syndrome, scleroderma, melanoma-associated leukoderma, chronic mucocutaneous candidiasis, and autoimmune disorders (including Grave's disease, **diabetes mellitus** (page 152), **pernicious anemia** (page 601), and Addison's disease). Rarely, skin transplants may be necessary.

### Nutritional supplements that may be helpful

Supplementation with the amino acid **L-phenylalanine** (page 568) (LPA) may have value when combined with ultraviolet (UVA) light therapy. Several clinical trials, including one double-blind trial, indicated that LPA (50 mg per 2.2 pounds of body weight per day—3,500 mg per day for a 154-pound person—or less) increased the extent of repigmentation induced by UVA therapy. LPA alone also produced a more modest repigmentation in some people.<sup>2</sup> A study of vitiligo in children reported that LPA plus UVA was an effective treatment in a majority of the children.<sup>3</sup>

A group of Spanish doctors reported on their experience using LPA over a six-year period. Some of the 171 people with vitiligo received LPA (50 or 100 mg per 2.2 pounds body weight per day) for up to three years. Between April and October of each year, participants also applied a 10% LPA gel, prior to exposing their skin to the sun for 30 minutes. Some improvement was seen in 83% of participants, and the results were rated as good in 57% (75% improvement or better).<sup>4</sup>

A clinical report describes the use of vitamin supplements in the treatment of vitiligo.<sup>5</sup> **Folic acid** (page 520) and/or **vitamin B<sub>12</sub>** (page 601) and **vitamin C** (page 604) levels were abnormally low in most of the 15 people studied. Supplementation with large amounts of folic acid (1–10 mg per day), along with vitamin C (1 gram per day) and intramuscular vitamin B<sub>12</sub> injections (1,000 mcg every two weeks), produced marked repigmentation in eight people. These improvements became apparent after three months, but complete repigmentation required one to two years of continuous supplementation. In another study of people with vitiligo, oral supplementation with folic acid (10 mg per day) and vitamin B<sub>12</sub> (2,000 mcg per day), combined with sun exposure, resulted in some repigmentation

after three to six months in about half of the participants.<sup>6</sup> This combined regimen was more effective than either vitamin supplementation or sun exposure alone.

When used topically in combination with sun exposure, a pharmaceutical form of **vitamin D** (page 607), called calcipotriol, may be effective in stimulating repigmentation in children with vitiligo. In a preliminary study, children applied a cream containing calcipotriol daily and exposed themselves to sunlight for 10–15 minutes the following morning.<sup>7</sup> After 11 months, marked to complete repigmentation occurred in 55% of the children, moderate repigmentation occurred in 22%, and little or no improvement was seen in 22%. None of the children developed new areas of vitiligo. The first evidence of repigmentation occurred within 6 to 12 weeks in the majority of the children. All participants tolerated the cream well, with approximately 17% complaining of mild, transient skin irritation. Calcipotriol is a prescription medication to be used only under the supervision of a doctor. It is not known whether vitamin D as a dietary supplement has any effect on vitiligo.

In one early report, lack of stomach acid (achlorhydria) was associated with vitiligo. Supplementation with dilute hydrochloric acid after meals resulted in gradual repigmentation of the skin (after one year or more).<sup>8</sup> Hydrochloric acid, or its more modern counterpart **betaine HCl** (page 473), should be taken only under the supervision of a doctor.

Another early report described the use of **PABA** (page 567) (para-aminobenzoic acid)—a compound commonly found in **B-complex vitamins** (page 603)—for vitiligo. Consistent use of 100 mg of PABA three or four times per day, along with an injectable form of PABA and a variety of hormones tailored to individual needs, resulted, in many cases, in repigmentation of areas affected by vitiligo.<sup>9</sup>

### Are there any side effects or interactions?

Refer to the individual supplement for information about any side effects or interactions.

### Herbs that may be helpful

In a double-blind study of 52 people with slowly spreading vitiligo, supplementation with *Ginkgo biloba* extract (standardized to contain 24% ginkgoflavonglycosides), in the amount of 40 mg three times per day for up to six months, resulted in marked to complete repigmentation in 40% of cases, compared with only 9% among those receiving a placebo.<sup>10</sup>

An extract from khella (*Ammi visnaga*) may be useful in repigmenting the skin of people with vitiligo. Khellin, the active constituent, appears to work like psoralen drugs—it stimulates repigmentation of the skin by increasing sensitivity of remaining melanocytes to sunlight. Studies have used 120–160 mg of khellin per day.<sup>11</sup>

In preliminary trial, **Picrorhiza** (page 728), in combination with the drug methoxsalen and sun exposure, was reported to hasten recovery in people with vitiligo compared with use of methoxsalen and sun exposure alone.<sup>12</sup> Between 400 and 1,500 mg of powdered, encapsulated picrorhiza per day has been used in a variety of studies.

#### *Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

#### **Holistic approaches that may be helpful**

People with vitiligo have occasionally improved using hypnosis along with other treatments.<sup>13</sup>

## WARTS

Warts are a common abnormal skin growths caused by one of many types of human papilloma virus, which infects the outer layer of skin.

Common warts (*verruca vulgaris*) can appear on any part of the body but are more common on the fingers, hands, and arms. They are most common in people 30 years old or younger, but can occur at any age and are almost universal in the population. Other types of warts also exist, including flat warts, genital warts, laryngeal papillomas, and others.

#### CHECKLIST FOR WARTS

Rating	Nutritional Supplements	Herbs
★★★	Zinc (page 614) (oral)	Garlic (page 679) (topical application)
★☆☆		Greater celandine (page 684)

#### **What are the symptoms of warts?**

Appearance and size of warts depend on the location and the amount of irritation and trauma. Common warts are sharply demarcated, rough-surfaced, round or

irregular in shape, firm, and either light gray, yellow, brown, or gray-black in color. They are small nodules ranging in size from 2–10 mm in diameter. Plantar warts (on the bottoms of the feet) are flattened and may be exquisitely tender. Flat warts, more common in children and young adults, are smooth, flat-topped yellow-brown elevations, most often seen on the face and along scratch marks. Genital warts (also called condyloma acuminata or venereal warts) are soft, moist, small pink or gray polyps that enlarge and are usually found in clusters on the anus and the warmer, moister areas of the female and male genitalia. Genital warts caused by HPV are considered a major cause of **cervical dysplasia** (page 3) and cervical cancer. All warts are contagious.

#### **Medical treatments**

Over the counter drugs used to treat common warts contain salicylic acid (Compound W, Dr Scholl's Wart Remover Kit, Mosco) and are applied topically on a daily basis.

Prescription medications are available to treat genital warts. They include podofilox (Condylox) and podophyllum resin (Podocon-25). The latter drug is only to be applied by a physician.

A protective pad may be worn to relieve the pain of plantar warts. In some cases, doctors may recommend removal of the wart using various procedures such as freezing with liquid nitrogen (cryotherapy), conventional surgery, laser surgery, or applying an electrical current to dry the wart (electrodesiccation with curettage).

#### **Dietary changes that may be helpful**

A preliminary study reported that the weekly consumption of two to four alcoholic drinks nearly doubled the risk of developing genital warts.<sup>1</sup> Those who consumed more than five alcoholic drinks had a more than doubled risk of developing genital warts. A case report of a 19-year-old with a urinary-tract wart found that abstinence from a high intake of pork led to a regression of the wart.<sup>2</sup>

#### **Lifestyle changes that may be helpful**

Warts can be spread by contact, and the transmission can occur between two people as well as between different parts of the body of the same person. To prevent the spread of the virus, warts should not be scratched. Genital warts are spread by sexual contact.

A study of **HIV** (page 239)-infected and HIV-negative women found that current smokers were over five

times more likely to develop genital warts than non-smokers.<sup>3</sup>

### Nutritional supplements that may be helpful

In a double-blind study, supplementation with oral **zinc** (page 614), in the form of zinc sulfate, for two months resulted in complete disappearance of warts in 87% of people treated, whereas none of those receiving a placebo improved.<sup>4</sup> The amount of zinc used was based on body weight, with a maximum of 135 mg per day. These large amounts of zinc should be used under the supervision of a doctor. Side effects included nausea, vomiting, and mild abdominal pain.

#### *Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

### Herbs that may be helpful

In a preliminary trial, topical application of garlic cloves was used successfully to treat warts in a group of children. A clove was cut in half each night and the flat edge of the clove was rubbed onto each of the warts, carefully cleaning the surrounding areas, so as not to spread any garlic juice. The areas were covered overnight with Band-Aids or waterproof tape and were washed in the morning. In all cases, the warts cleared completely after an average of nine weeks.<sup>5</sup>

Herbalists have sometimes recommended the use of **greater celandine** (page 684) (*Chelidonium majus*) for the topical treatment of warts.<sup>6</sup> The milky juice from the fresh plant is typically applied to the wart once daily and allowed to dry.

#### *Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

### Holistic approaches that may be helpful

Distant healing is a conscious, dedicated act of mental activity that attempts to benefit another person's physical or emotional well-being at a distance. A controlled study found that distant healing by an experienced healer for six weeks had no effect on the number or size of warts.<sup>7</sup>

A controlled study found that the application of 122°F heat from a heat pad for 30 seconds led to regression in 25 warts.<sup>8</sup> After 15 weeks, none of the regressed warts had regrown.

Hypnosis is a widely recognized treatment for warts. One controlled trial found that twice-weekly hypnosis

sessions resulted in greater wart disappearance than did medication, placebo, or no treatment after six weeks of therapy.<sup>9</sup>

## WEIGHT LOSS AND OBESITY

**See also:** Childhood Obesity (page 107)

### What do I need to know?

Self-care for weight loss and obesity can be approached in a number of ways—but it can be hard to know just where to start. To make it easier, our doctors recommend trying these simple steps first:

#### *Find a diet that fits*

For long-term success, choose a healthy diet that you can stay with

#### *Find support*

Improve your chances for long-term weight loss by joining a group while you adjust to new diet and exercise habits

#### *Create a custom exercise plan*

Exercise you truly enjoy is that much easier to stick to, so find activities that fit your personal style, fitness level, and work-out opportunities

#### *Get a boost from pyruvate*

Combining exercise with 6 to 10 grams a day of pyruvate may help speed up your metabolism

#### *Try 5-HTP (5-hydroxytryptophan)*

Taking 600 to 900 mg a day may help curb your appetite

#### *Aim for total nutrition with a multivitamin-mineral supplement*

Extra vitamins and minerals will help ensure your body gets the nutrition it needs, especially if you are avoiding certain foods

### About weight loss and obesity

About two-thirds of the adult U.S. population is overweight.<sup>1</sup> Almost one-third not only exceeds ideal weight, but also meets the clinical criteria for obesity. In the 1990s, rates of obesity more than doubled, and are currently rising by over 5% per year.<sup>2, 3</sup> Excess body weight is implicated as a risk factor for many different disorders, including **heart disease** (page 98), **diabetes** (page 152), several **cancers** (page 87) (such as **breast cancer** [page 65] in postmenopausal women, and can-

cers of the uterus, **colon** [page 123], and kidney), prostate enlargement (**BPH** [page 58]), **female infertility** (page 187), uterine fibroids, and **gallstones** (page 193), as well as several disorders of pregnancy, including gestational diabetes, preeclampsia, and gestational hypertension.<sup>4</sup> The location of excess body fat may affect the amount of health risk associated with overweight. Increased abdominal fat, which can be estimated by waist size, may be especially hazardous to long-term health.<sup>5,6</sup>

For overweight women, weight loss can significantly improve physical health. A four-year study of over 40,000 women found that weight loss in overweight women was associated with improved physical function and vitality as well as decreased bodily pain.<sup>7</sup> The risk of death from all causes, cardiovascular disease, cancer, or other diseases increases in overweight men and women in all age groups.<sup>8</sup> Losing weight and keeping it off is, unfortunately, very difficult for most people.<sup>9,10</sup> However, repeated weight loss followed by weight regain may be unhealthy, as it has been associated with increased heart disease risk factors and bone loss in some studies.<sup>11,12</sup> Rather than focusing on weight loss as the most important health outcome of a change in diet or lifestyle, some doctors advocate paying more attention to overall fitness and reduction in known risk factors for heart disease and other health hazards.<sup>13</sup>

Excess body mass has the one advantage of increasing bone mass—a protection against **osteoporosis** (page 333). Probably because of this, researchers have been able to show that people who successfully lose weight have greater loss of bone compared with those who do not lose weight.<sup>14</sup> People who lose weight should, therefore, pay more attention to preventing osteoporosis.

### Medical treatments

Over-the-counter products such as Dexatrim Natural No Caffeine and Dexatrim Natural No Ephedrine are available to assist with weight loss.

Prescription medications commonly prescribed for weight loss include sibutramine (Meridia), orlistat (Xenical), and phentermine (Fastin, Ionamin). Stimulants, such as dextroamphetamine (Dexedrine) and methamphetamine (Desoxyn), are occasionally used.

Other treatment typically includes dietary changes to limit fat and calorie intake, increased exercise, and changes in eating habits or patterns. Severe cases might require surgical options to reduce the size of the stomach or to bypass a portion of the stomach and intestines.

### CHECKLIST FOR WEIGHT LOSS AND OBESITY

Rating	Nutritional Supplements	Herbs
★★★	<b>Multivitamin-mineral</b> (page 559) (for very-low-calorie diets) <b>Pyruvate</b> (page 580)	
★★☆	<b>Beta-hydroxy beta-methylbutyrate</b> ( <b>HMB</b> ) (page 534) (for improving body composition only) <b>Calcium</b> (page 483) <b>Conjugated linoleic acid (CLA)</b> (page 499) <b>5-HTP</b> (page 459) <b>Fiber</b> (page 512) <b>Glucomannan</b> (page 526) <b>7-KETO</b> (page 460)	<b>Cayenne</b> (page 654) <b>Green tea</b> (page 686) <b>Yohimbe</b> (page 764)

### Dietary changes that may be helpful

#### *Breast-feeding* (page 74)

In a preliminary study, breast-feeding during infancy was associated with a reduced risk of developing obesity during early childhood (ages three to four years).<sup>15</sup>

In a preliminary study, overweight individuals who adhered to a very-low-carbohydrate diet (25 grams per day initially, increased to 50 grams per day after a certain weight-loss target was achieved), with no limit on total calorie intake, lost on average more than 10% of their body weight over a six-month period.<sup>16</sup> The participants also engaged in aerobic exercise at least three times a week, so it is not clear how much of the weight loss was due to the diet. Blood tests taken during the study suggested that the low-carbohydrate diet induced

a condition called mild metabolic acidosis, indicating that long-term consumption of this diet may not be entirely safe. Individuals wishing to consume a very-low-carbohydrate diet for weight loss or for other reasons should be monitored by a doctor.

#### *Calorie restriction*

Calories in the diet come from fat, carbohydrate, protein, or alcohol. Weight-loss diets are typically designed to limit calories either by restricting certain foods that are thought to result in increased calorie intake, and/or by emphasizing foods that are believed to result in reduced calorie intake. Some currently popular diets restrict fat while emphasizing fiber and a balanced intake of healthful foods. Others restrict carbohydrates, either to extremely low amounts as in the Atkins diet, or to a lesser degree, emphasizing foods low in the glycemic index or high in protein. Discussions of the research on these diets follow; however, it should be remembered that no diet has been proven effective for long-term weight loss, and many people find it difficult to stay on most diets.<sup>17, 18</sup>

Low-fat, low-calorie, high-fiber, balanced diets are recommended by many doctors for weight loss.<sup>19</sup> According to controlled studies, when people are allowed to eat as much food as they desire on a low-fat diet, they tend to lose more weight than people eating a regular diet.<sup>20</sup> However, low-fat diets have not been shown to be more effective than other weight-loss diets that restrict calories.<sup>21</sup> Nonetheless, a low-fat, high-fiber, balanced diet has additional potential benefits, such as reducing the risk of chronic diseases including heart disease and cancer.<sup>22, 23</sup>

Preliminary research indicates that people who successfully lost weight got fewer of their total calories from fat and more of them from protein foods. They also ate fewer snacks of low nutritional quality and got more of their calories from "hot meals of good quality."<sup>24</sup> Other preliminary studies find that dieters who maintain long-term weight loss report using fat restriction and eating a regular breakfast as key strategies in their success.<sup>25, 26</sup>

#### *Low-carbohydrate, high-protein diets*

Low-carbohydrate, high-fat diets such as the Atkins diet are very popular among people trying to lose weight. In a preliminary study, overweight individuals who adhered to a very-low-carbohydrate diet (25 grams per day initially, increased to 50 grams per day after a certain weight loss target was achieved), with no limit on total calorie intake, lost on average more than 10% of their body weight over a six-month period.<sup>27</sup> The participants also engaged in aerobic exercise at least

three times a week, so it is not clear how much of the weight loss was due to the diet. An analysis of other preliminary studies of this type of diet concluded that its effectiveness is primarily due to reduced calorie intake.<sup>28</sup> Recently, three controlled trials found people using low-carbohydrate, high-fat diets lost more weight in six months than those using diets low in fat and calories.<sup>29, 30, 31</sup> However, 20% to 40% of these dieters did not stay on their diets, and were not counted in the results. In addition, one of these trials continued for an additional six months, at the end of which there was no longer a significant difference in weight loss between the two diet groups. A recent 12-week controlled trial found that overweight adolescents also lost more weight with a low-carbohydrate diet than with a low-fat diet, even though they consumed 50% more calories than did the children on the low-fat diet.<sup>32</sup> That study suggests that the weight loss occurring on the Atkins diet is not due entirely to calorie restriction. Blood tests suggest that low-carbohydrate diets induce a condition called mild metabolic acidosis, which might increase the risk of osteoporosis and kidney stones.

The effect of low-carbohydrate diets on cardiovascular risk is also an unresolved issue. The short-term studies discussed above found that blood cholesterol levels did not worsen with these diets. Other heart-disease risk factors (triglyceride levels and insulin sensitivity) actually improved with a low-carbohydrate diet. Some studies, however, have shown a worsening of certain cardiovascular risk factors in people using a low-carbohydrate, high-fat diet for up to one year. Adverse changes included increases in blood levels of homocysteine, lipoprotein(a), and fibrinogen,<sup>33</sup> and a decrease in blood flow to the heart.<sup>34</sup> Individuals wishing to consume a very-low-carbohydrate diet for weight loss or for other reasons should be monitored by a doctor.

Some research has investigated weight-loss diets that are high in protein, but moderate in fat and not as low in carbohydrate content as the diets discussed above. While this type of diet does not usually lead to greater weight loss than other diets when calorie intakes are kept equal,<sup>35</sup> one controlled trial found greater body fat loss in women eating a diet almost equal in calories and fat but approximately twice as high in protein and lower in carbohydrate compared with a control group's diet.<sup>36</sup> Another controlled trial compared two diets similar in fat content but different in protein and carbohydrate content. People allowed to eat freely from the higher protein diet (25% of calories from protein, 45% calories from carbohydrate) consumed fewer calories and lost more weight compared with people eating the

lower protein diet (12% of calories from protein, 59% calories from carbohydrate).<sup>37</sup>

#### *Low glycemic index foods*

Diets that emphasize choosing foods with a low glycemic index have been shown to help control appetite in some,<sup>38, 39, 40</sup> though not all,<sup>41</sup> controlled studies. A controlled study in two phases found no difference in weight loss between a low and a high glycemic index diet in the first 12-week phase, but when the diets were switched for a second 12-week phase, the low glycemic index diet was significantly more effective for weight loss.<sup>42</sup> A preliminary study reported that obese children using a low glycemic index diet lost more weight compared with a similar group using a low-fat diet.<sup>43</sup>

#### *Fiber*

Adequate amounts of dietary fiber are believed to be important for people wishing to lose weight. Fiber adds bulk to the diet and tends to produce a sense of fullness, helping people consume fewer calories.<sup>44</sup> While research on the effect of fiber intake on weight loss has not produced consistent results,<sup>45</sup> a recent review of weight-loss trials that did not restrict calories concluded that higher fiber diets improved weight-loss results, especially in people who were overweight.<sup>46</sup>

#### *Stabilizing food sensitivities*

Although the relationship between **food sensitivities** (page 14) and body weight remains uncertain, according to one researcher, chronic food allergy may lead to overeating and obesity.<sup>47</sup>

#### *Long-term changes*

People who go on and off diets frequently complain that it takes fewer calories to produce weight gain with each weight fluctuation. Evidence now clearly demonstrates that the body gets “stingier” in its use of calories after each diet.<sup>48</sup> This means it becomes easier to gain weight and harder to lose it the next time. Dietary changes need to be long term.

#### **Lifestyle changes that may be helpful**

##### *Support*

Many doctors give overweight patients a pill, a pep talk, and a pamphlet about diet and exercise, but that combination leads only to minor weight loss.<sup>49</sup> When overweight people attend group sessions aimed at changing eating and exercise patterns, keep daily records of food intake and exercise, and eat a specific low-calorie diet the outcome is much more successful. Group sessions where participants are given information and help on

how to make lifestyle changes appear to improve the chances of losing weight and keeping it off. Such changes may include shopping from a list, storing foods out of sight, keeping portion sizes under control, and avoiding fast-food restaurants.

#### *Exercise*

According to most short-term studies, the effect of exercise alone (without dietary restriction) on weight loss is small,<sup>50, 51</sup> partly because muscle mass often increases even while fat tissue is reduced,<sup>52</sup> and perhaps because some exercising people will experience increased appetites. The long-term effect of regular exercise on weight loss is much better, and exercise appears to help people maintain weight loss.<sup>53, 54</sup> People who have successfully maintained weight loss for over two years report continuing high levels of physical activity.<sup>55</sup> Combining exercise with healthier eating habits results in the best short- and long-term effects on weight loss,<sup>56, 57</sup> and should reduce the risk of many serious diseases.<sup>58, 59, 60</sup>

#### *Avoid weight cycling*

People who experience “weight cycling” (repetitive weight loss and gain) have a tendency toward **binge eating** (page 174) (periods of compulsive overeating, but without the self-induced vomiting seen in **bulimia** [page 174]), according to a review of numerous studies focusing on weight loss.<sup>61</sup> The researchers also found an association between weight cycling and **depression** (page 145) or poor body image. The most successful weight-loss programs (in which weight stays off, mood stays even, and no binge eating occurs) appear to use a combination of moderate caloric restriction, moderate exercise, and behavior modification, including examination and adjustment of eating habits.

#### **Nutritional supplements that may be helpful**

##### *Multiple vitamin minerals (page 559)*

Diets that are low in total calories may not contain adequate amounts of various vitamins and minerals. For that reason, taking a multiple vitamin-mineral supplement is advocated by proponents of many types of weight-loss programs, and is essential when calorie intake will be less than 1,100 calories per day.<sup>62</sup>

##### *Pyruvate (page 580)*

Pyruvate, a compound that occurs naturally in the body, might aid weight-loss efforts.<sup>63</sup> A controlled trial found that pyruvate supplements (22 to 44 grams per day) enhanced weight loss and resulted in a greater reduction of body fat in overweight adults consuming a low-fat diet.<sup>64</sup> Three controlled trials combining 6 to

10 grams per day of pyruvate with an exercise program reported greater effects on weight loss and body fat than that seen with a placebo plus the exercise program.<sup>65, 66, 67</sup> Animal studies suggest that pyruvate supplementation leads to weight loss by increasing the resting metabolic rate.<sup>68</sup>

### **5-HTP (page 459)**

5-hydroxytryptophan (5-HTP), the precursor to the chemical messenger (neurotransmitter) serotonin, has been shown in three short-term controlled trials to reduce appetite and to promote weight loss.<sup>69, 70, 71</sup> In one of these trials (a 12-week double-blind trial), overweight women who took 600 to 900 mg of 5-HTP per day lost significantly more weight than did women who received a placebo.<sup>72</sup> In a double-blind trial with no dietary restrictions, obese people with type 2 (non-insulin-dependent) **diabetes** (page 152) who took 750 mg per day of 5-HTP for two weeks significantly reduced their carbohydrate and fat intake. Average weight loss in two weeks was 4.6 pounds, compared with 0.2 pounds in the placebo group.<sup>73</sup>

### **7-KETO (page 460)**

The ability of 7-KETO (3-acetyl-7-oxo-dehydroepiandrosterone), a substance related to **DHEA** (page 503), to promote weight loss in overweight people has been investigated in one double-blind trial.<sup>74</sup> Participants in the trial were advised to exercise three times per week for 45 minutes and to eat an 1,800-calorie-per-day diet. Each person was given either a placebo or 100 mg of 7-KETO twice daily. After eight weeks, those receiving 7-KETO had lost more weight and lowered their percentage of body fat further compared to those taking a placebo. These results may have been due to increases in levels of a thyroid hormone (T3) that plays a major role in determining a person's metabolic rate, although the levels of T3 did not exceed the normal range.

### **HMB (page 534)**

Biochemical and animal research show that HMB has a role in protein synthesis and might, therefore, improve muscle growth and overall body composition when given as a supplement. However, double-blind human research suggests that HMB may only be effective when combined with an exercise program in people who are not already highly trained athletes. Double-blind trials found no effect of 3 to 6 grams per day of HMB on body weight, body fat, or overall body composition in weight-training football players or other trained athletes.<sup>75, 76, 77, 78, 79</sup> However, one double-blind study found that 3 grams per day of HMB increased the

amount of body fat lost by 70-year-old adults who were participating in a strength-training program for the first time.<sup>80</sup> A double-blind study of young men with no strength-training experience reported greater improvements in muscle mass (but not in percentage body fat) when HMB was used in the amount of 17 mg per pound of body weight per day.<sup>81</sup> However, another group of men in the same study given twice as much HMB did not experience any changes in body composition.

### **Calcium (page 483)**

In a study of obese people consuming a low-calorie diet for 24 weeks, those receiving a calcium supplement (800 mg per day) lost significantly more weight than those given a placebo.<sup>82</sup> Calcium was effective when provided either as a supplement, or in the form of dairy products. In a second study, however, the amount of weight loss resulting from calcium supplementation (1,000 mg per day) was small and not statistically significant.<sup>83</sup> In that study, participants' typical diets contained more calcium than in the study in which calcium supplementation was more effective. Thus, it is possible that calcium supplementation enhances weight loss only when the diet is low in calcium.

### **CLA (page 499)**

A double-blind trial found that exercising individuals taking 1,800 mg per day of conjugated linoleic acid (CLA) lost more body fat after 12 weeks than did a similar group taking a placebo.<sup>84</sup> However, two other studies found that amounts of CLA from 0.7 to 3.0 grams per day did not affect body composition.<sup>85, 86</sup> Most double-blind trials have found that larger amounts of CLA, 3.4 to 4.2 grams per day, do reduce body fat;<sup>87, 88, 89</sup> however, one double-blind study of experienced strength-training athletes reported no effect of 6 grams per day of CLA on body fat, muscle mass, or strength improvement.<sup>90</sup>

### **Fiber (page 512)**

Fiber supplements are one way to add fiber to a weight-loss diet. Several trials have shown that supplementation with fiber from a variety of sources accelerated weight loss in people who were following a low-calorie diet.<sup>91, 92, 93, 94</sup> Other researchers found, however, that fiber supplements had no effect on body weight, even though it resulted in a reduction in food intake.<sup>95</sup>

### **Glucomannan (page 526)**

Supplementation with 3 to 4 grams per day of a bulking agent called glucomannan, with or without a low-calorie diet, has promoted weight loss in overweight

adults,<sup>96, 97, 98</sup> while 2 to 3 grams per day was effective in a group of obese adolescents in another controlled trial.<sup>99</sup>

#### **HCA (page 535)**

(-)-Hydroxycitric acid (HCA), extracted from the rind of the *Garcinia cambogia* fruit grown in Southeast Asia, has a chemical composition similar to that of citric acid (the primary acid in oranges and other citrus fruits). Preliminary studies in animals suggest that HCA may be a useful weight-loss aid.<sup>100, 101</sup> HCA has been demonstrated in the laboratory (but not yet in clinical trials with people) to reduce the conversion of carbohydrates into stored fat by inhibiting certain enzyme processes.<sup>102, 103</sup> Animal research indicates that HCA suppresses appetite and induces weight loss.<sup>104, 105, 106, 107</sup> However, a double-blind trial found that people who took 1,500 mg per day of HCA while eating a low-calorie diet for 12 weeks lost no more weight than those taking a placebo.<sup>108</sup> A double-blind trial of *Garcinia cambogia* (2.4 grams of dry extract, containing 50% hydroxycitric acid) found that the extract did not increase energy expenditure; it was therefore concluded that this extract showed little potential for the treatment of obesity at this amount.<sup>109</sup> Nonetheless, another double-blind trial found that using the same amount of *Garcinia cambogia* extract significantly improved the results of a weight-loss diet, even though the amount of food intake was not affected.<sup>110</sup>

#### **Amylase inhibitors (page 466)**

Amylase inhibitors are also known as starch blockers because they contain substances that prevent dietary starches from being absorbed by the body. Starches are complex carbohydrates that cannot be absorbed unless they are first broken down by the digestive enzyme amylase and other, secondary, enzymes.<sup>111, 112</sup> When starch blockers were first developed years ago, they were found not to be potent enough to prevent the absorption of a significant amount of carbohydrate.<sup>113, 114, 115, 116</sup> Recently, highly concentrated starch blockers have been shown to be more effective,<sup>117, 118, 119</sup> but no published human studies exist investigating their usefulness for weight loss.

#### **Blue-green algae (page 474)**

Blue-green algae, or spirulina, is a rich source of protein, vitamins, minerals, and essential fatty acids. In one double-blind trial, overweight people who took 2.8 grams of spirulina three times per day for four weeks experienced only small and statistically nonsignificant weight loss.<sup>120</sup> Thus, although spirulina has been promoted as a weight-loss aid, the scientific evidence supporting its use for this purpose is weak.

#### **Chitosan (page 491)**

Chitosan is a fiber-like substance extracted from the shells of crustaceans such as shrimp and crab. Animal studies suggested that chitosan supplementation reduces fat absorption, but controlled human trials have found no impairment of fat absorption from supplementation with 2,700 mg of chitosan per day for seven days or 5,250 mg per day for four days.<sup>121, 122</sup> A double-blind study in Poland found that people taking 1,500 mg of chitosan three times per day during a weight-loss program lost significantly more weight than did people taking a placebo with the same program.<sup>123</sup> Other studies using smaller amounts of chitosan have reported no effects on weight loss.<sup>124, 125, 126</sup>

#### **Chromium (page 493)**

The mineral chromium plays an essential role in the metabolism of carbohydrates and fats and in the action of insulin. Chromium, usually in a form called chromium picolinate, has been studied for its potential role in altering body composition. Chromium has primarily been studied in body builders, with conflicting results.<sup>127</sup> In people trying to lose weight, a double-blind study found that 600 mcg per day of niacin-bound chromium helped some participants lose more fat and less muscle.<sup>128</sup> However, three other double-blind trials have found no effect of chromium picolinate on weight loss,<sup>129, 130, 131</sup> though in one of these trials lean body mass that was lost during a weight-loss diet was restored by continuing to supplement chromium after the diet. A recent comprehensive review combining the results of ten published and unpublished double-blind studies concluded that chromium picolinate supplementation may have a small beneficial effect on weight loss.<sup>132</sup>

#### **DHEA (page 503)**

One double-blind trial found 100 mg per day of DHEA was effective for decreasing body fat in older men,<sup>133</sup> and another double-blind trial found 1,600 mg per day decreased body fat and increased muscle mass in younger men.<sup>134</sup> However, DHEA has not been effective for improving body composition in women or in other studies of men.<sup>135, 136, 137, 138, 139, 140, 141, 142</sup>

#### **Guar gum**

Guar gum, another type of fiber supplement, has not been effective in controlled studies for weight loss or weight maintenance.<sup>143, 144, 145</sup>

#### **L-carnitine (page 543)**

The amino acid L-carnitine is thought to be potentially helpful for weight loss because of its role in fat metabo-

lism. In a preliminary study of overweight adolescents participating in a diet and exercise program, those who took 1,000 mg of L-carnitine per day for three months lost significantly more weight than those who took a placebo.<sup>146</sup> A weakness of this trial, however, was the fact that the average starting body weight differed considerably between the two groups. A double-blind trial found that adding 4,000 mg of L-carnitine per day to an exercise program did not result in weight loss in overweight women.<sup>147</sup>

#### **Soy (page 586)**

Animal and human studies have suggested that when soy is used as a source of dietary protein, it may have several biological effects on the body that might help with weight loss.<sup>148</sup> A preliminary study found that people trying to lose weight using a meal-replacement formula containing soy protein lost more weight than a group not using any formula.<sup>149</sup> However, controlled studies comparing soy protein with other protein sources in weight-loss diets have not found any advantage of soy.<sup>150, 151, 152</sup> When soy protein is used for other health benefits, typical daily intake is 20 grams per day or more.

#### **Whey protein (page 613)**

Whey protein may aid weight loss due to its effect on appetite. In a preliminary study, people were given 48 grams of either whey protein or milk protein (casein). Whey consumption resulted in more hunger satisfaction and reduced the amount of food eaten 90 minutes later compared with casein consumption.<sup>153</sup> However, a double-blind study found that men taking 1.5 grams per 2.2 lbs body weight per day of whey protein for 12 weeks along with a low-calorie diet and a strength training exercise program lost the same amount of weight and body fat as did a control group that followed a similar program, but took a casein supplement instead of whey protein.<sup>154</sup>

#### *Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

#### **Herbs that may be helpful**

##### **Cayenne (page 634)**

Research has suggested that incorporating cayenne pepper into the diet may help people lose weight. Controlled studies report that adding 6 to 10 grams of cayenne to a meal or 28 grams to an entire day's diet reduces hunger after meals and reduces calories consumed during subsequent meals.<sup>155, 156</sup> Other con-

trolled studies have reported that calorie burning by the body increases slightly when 10 grams of cayenne is added to a meal or 28 grams is added to an entire day's diet.<sup>157, 158, 159</sup> However, no studies have been done to see if regularly adding cayenne to the diet has any effect on weight loss.

##### **Green tea (page 686)**

Green tea extract rich in polyphenols (epigallocatechin gallate, or EGCG) may support a weight-loss program by increasing energy expenditure or by inhibiting the digestion of fat in the intestine.<sup>160, 161</sup> Healthy young men who took two green tea capsules (containing a total of 50 mg of caffeine and 90 mg of EGCG) three times a day had a significantly greater energy expenditure and fat oxidation than those who took caffeine alone or a placebo.<sup>162</sup> In a preliminary study of moderately obese individuals, administration of a specific green tea extract (AR25) resulted in a 4.6% reduction in average body weight after 12 weeks.<sup>163</sup> The amount of green tea extract used in this study supplied daily 270 mg of EGCG and 150 mg of caffeine. While caffeine is known to stimulate metabolism, it appears that other substances besides caffeine were responsible for at least part of the weight loss. Although the extract produced few side effects, one individual had abnormal liver function tests during the study. In another study, consuming approximately 12 ounces of oolong tea (a semifermented version of green tea) daily for 12 weeks reduced waist circumference and the amount of body fat in a group of normal-weight to overweight men.<sup>164</sup> Additional studies are needed to confirm the safety and effectiveness of green tea extracts for promoting weight loss.

##### **Yohimbine (page 764)**

The ability of yohimbine, a chemical found in yohimbe bark, to stimulate the nervous system,<sup>165, 166</sup> and to promote the release of fat from fat cells,<sup>167, 168</sup> has led to claims that it might help weight loss by raising metabolic rate, reducing appetite, or increase fat burning. Although a preliminary trial found yohimbine ineffective for weight loss, a double-blind study found that women taking 5 mg of yohimbine four times per day along with a weight-loss diet lost significantly more weight than those taking a placebo with the same diet after three weeks.<sup>169</sup> However, a similar study using 18 mg per day of yohimbine for eight weeks reported no benefit to weight loss compared with a placebo.<sup>170</sup> A double-blind study of men who were not dieting reported no effect of up to 43 mg per day of yohimbine

on weight or body composition after six months.<sup>171</sup> All of these studies used pure yohimbine; no study has tested the effects of yohimbe herb on weight loss.

#### **Bitter orange (page 635)**

Although historically used to stimulate appetite, bitter orange is frequently found in modern weight-loss formulas because synephrine is similar to the compound ephedrine, which is known to promote weight loss. In one study of 23 overweight adults, participants taking a daily intake of bitter orange (975 mg) combined with caffeine (525 mg) and St. John's wort (*Hypericum perforatum*, 900 mg) for six weeks lost significantly more body weight and fat than the control group.<sup>172</sup> No adverse effects on heart rate or blood pressure were found. Bitter orange standardized to contain 4% to 6% synephrine had an anti-obesity effect in rats. However, the amount used to achieve this effect was accompanied by cardiovascular toxicity and mortality.<sup>173</sup>

#### **Coleus (page 660)**

Although no clinical trials have been done, there are modern references to use of the herb coleus for weight loss.<sup>174</sup> Coleus extracts standardized to 18% forskolin are available, and 50 to 100 mg can be taken two to three times per day. Fluid extract can be taken in the amount of 2 to 4 ml three times per day.

#### **Guarana (page 687)**

The herb guaraná contains caffeine and the closely related alkaloids theobromine and theophylline; these compounds may curb appetite and increase weight loss. Caffeine's effects are well known and include central nervous system stimulation, increased metabolic rate, and a mild diuretic effect.<sup>175</sup> In a double-blind trial, 200 mg per day of caffeine was, however, no more effective than a placebo in promoting weight loss.<sup>176</sup> Because of concerns about potential adverse effects, many doctors do not advocate using caffeine or caffeine-like substances to reduce weight.

#### **Guggul (page 688)**

Coupled with exercise in a double-blind trial, a combination of guggul, phosphate salts, hydroxycitrate, and **tyrosine** (page 465) has been shown to improve mood with a slight tendency to improve weight loss in overweight adults.<sup>177</sup> Daily recommendations for guggul are typically based on the amount of guggulsterones in the extract. A common intake of guggulsterones is 25 mg three times per day. Most guggul extracts contain 5% to 10% guggulsterones and can be taken daily for 12 to 24 weeks.

#### *Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

## **WILSON'S DISEASE**

Wilson's disease is a genetic disorder that results in excessive accumulation of **copper** (page 499) in many parts of the body, particularly the liver.

This condition is readily treatable, but if Wilson's disease is left untreated, it can be fatal.

#### **CHECKLIST FOR WILSON'S DISEASE**

Rating	Nutritional Supplements	Herbs
★★★	Zinc (page 614)	

#### **What are the symptoms of Wilson's disease?**

Wilson's disease is initially silent and may first be noticed as fatigue, absent menstrual periods in premenopausal women, or repeated and unexplained spontaneous abortions. In more advanced stages, there may be headaches, tremors, uncoordinated limb movements, unsteady gait, drooling, difficulty swallowing, and joint pain. There also may also be strange thought patterns with unusual behaviors.

#### **Medical treatments**

Over the counter **zinc** (page 614) supplements are sometimes used, but not in combination with the prescription medications used to treat Wilson's disease, due to interactions.

The prescription drug trientine (Syprine) is commonly used to remove excess copper. Oral penicillamine (Depen), given with vitamin B<sub>6</sub> to avoid depletion of the vitamin, is also used.

Healthcare providers also recommend a low copper diet.

#### **Dietary changes that may be helpful**

Most foods contain at least some copper, so it is not possible to avoid the metal completely. Foods high in copper, such as organ meats and oysters, should be eliminated from the diet. Some foods are relatively high in copper but are quite nutritious (e.g., nuts and legumes)—these foods should be eaten in moderation

by people with Wilson's disease. Grains contain significant amounts of copper but are important components of a healthful diet, and dietary restriction may be neither wise nor necessary, particularly if zinc is supplemented.

### Nutritional supplements that may be helpful

**Zinc** (page 614) is known for its ability to reduce copper absorption and has been used successfully in patients with Wilson's disease,<sup>1</sup> with some trials lasting for years.<sup>2, 3</sup> Researchers have called zinc a "remarkably effective and nontoxic therapy for Wilson's disease."<sup>4</sup> The U.S. Food and Drug Administration has approved the use of zinc to treat Wilson's disease for maintenance therapy following drug therapy, although some scientists recommend that it be considered for initial therapy as well.<sup>5</sup>

Zinc has also been used to keep normal **copper** (page 499) levels from rising in people with Wilson's disease who had previously been treated successfully with prescription drugs.<sup>6</sup> Zinc (50 mg taken three times per day) has been used for such maintenance therapy,<sup>7</sup> though some researchers have used the same amount of zinc to successfully treat people with Wilson's disease who had not received drug therapy.<sup>8</sup>

Zinc is so effective in lessening the body's burden of copper that a copper deficiency was reported in someone with Wilson's disease who took too much (480 mg per day) zinc.<sup>9</sup> Nonetheless, zinc may not help everyone with Wilson's disease. Sometimes increased copper levels can occur in the liver after zinc supplementation;<sup>10</sup> however, leading researchers believe this increase is temporary and may not be not harmful.<sup>11</sup>

Zinc supplementation (25 mg or 50 mg three times daily) has also been used to successfully treat pregnant women with Wilson's disease.<sup>12</sup> Management of Wilson's disease with zinc should only be undertaken with the close supervision of a doctor.

**Copper** (page 499) is present in several dietary supplements, especially multimineral and **multivitamin-mineral** (page 559) preparations. Supplements containing even small amounts of copper should be avoided by virtually all Wilson's disease patients.

### Are there any side effects or interactions?

Refer to the individual supplement for information about any side effects or interactions.

## YEAST INFECTION

**See also:** Chronic Candidiasis (page 109)

### What do I need to know?

Self-care for yeast infection can be approached in a number of ways—but it can be hard to know just where to start. To make it easier, our doctors recommend trying these simple steps first:

#### Ask your doctor about problem medicines

Find out whether you can avoid taking antibiotics, oral contraceptives, or adrenal corticosteroids (such as prednisone) that may lead to yeast infection

#### Switch to cotton underwear

Avoid the increased risks of yeast infection associated with nylon underwear and tights

#### Try beneficial bacteria

To prevent the overgrowth of yeast organisms, eat yogurt containing live acidophilus cultures daily, and use acidophilus topically as vaginal suppositories or a douche

### About yeast infection

Yeast infections usually result from an overgrowth of a species of fungus called *Candida albicans*. They can occur on the skin, under nails or mucous membranes of the mouth, vagina, bronchi, and lungs.

Vaginal yeast infections are one of the most common reasons that women consult healthcare professionals.

### CHECKLIST FOR YEAST INFECTION

Rating	Nutritional Supplements	Herbs
★★★	<b>Lactobacillus acidophilus</b> (page 575)	
★★☆	<b>Boric acid</b> (page 476)	
★☆☆		<b>Cinnamon</b> (page 659) <b>Echinacea</b> (page 669) <b>Oregano</b> (page 719) <b>Tea tree oil</b> (page 751)

### What are the symptoms of yeast infection?

Yeast infections are a type of **vaginitis** (page 438). The hallmark symptom of a yeast infection is itching of the

external and internal genitalia, which is often associated with a white discharge that can be thick and/or curdy (like cottage cheese). Severe infections lead to inflammation of the tissue and subsequent redness, swelling, and even pinpoint bleeding.

### Medical treatments

Over the counter drugs available to treat yeast infection caused by candida include clotrimazole (Gyne-Lotrimin, Mycelex), miconazole (Monistat), and butoconazole (Femstat).

Prescription drugs include oral fluconazole (Diflucan), nystatin (Mycostatin) vaginal tablets, terconazole (Terazol) vaginal cream, and butoconazole (Gynazole) vaginal cream. The antifungal creams may also be applied topically to the vulva (external genitalia) to help relieve itching.

### Dietary changes that may be helpful

Some doctors believe that a well-balanced diet low in fats, sugars, and refined foods is important for preventing vaginal infections caused by Candida. In one preliminary trial, avoidance of sugar, dairy products, and artificial sweeteners resulted in a sharp reduction in the incidence and severity of Candida vaginitis.<sup>1</sup> Many doctors advise women who have a yeast infection (or are predisposed to such infections), to limit their intake of sugar, fruit juices, and refined carbohydrates. For persistent or recurrent infections, some doctors recommend that fruit also be avoided.

Another trial found that dramatic increases in intake of several sugars in healthy people partially increased stool sample levels of Candida, but only in 12 out of 28 people.<sup>2</sup>

### Lifestyle changes that may be helpful

According to one study, yeast infections are three times more common in women who wear nylon underwear or tights, than in those who wear cotton underwear.<sup>3</sup> Additional predisposing factors for Candida infection include the use of antibiotics, oral contraceptives, or adrenal corticosteroids (such as prednisone).

Underlying health conditions that may predispose someone to Candida overgrowth include **pregnancy** (page 363), **diabetes** (page 152), and **HIV** (page 239) infection. **Allergies** (page 14) have also been reported to promote the development of recurrent yeast vaginitis. In a preliminary trial, when the allergens were

avoided and the allergies treated, the chronic recurrent yeast infections frequently resolved.<sup>4</sup> In most cases, sexual transmission does not play a role in yeast infection. However, in persistent cases, sexual transmission should be considered, and the sexual partner should be examined and treated.

### Nutritional supplements that may be helpful

*Lactobacillus acidophilus* (page 575) is a species of friendly bacteria that is an integral part of normal vaginal flora. Lactobacilli help to maintain the vaginal ecosystem by preventing the overgrowth of unfriendly bacteria and Candida. Lactobacilli produce lactic acid, which acts like a natural antibiotic.

*Lactobacillus acidophilus* can be taken orally in the form of acidophilus yogurt, or in capsules or powder. It can also be administered vaginally. In a controlled trial, women who consumed 8 ounces of *Lactobacillus acidophilus*-containing yogurt per day had a threefold decrease in the incidence of vaginal yeast infections and a reduction in the frequency of Candida colonization in the vagina.<sup>5</sup> In another trial, women who were predisposed to vaginal Candida infection because they were **HIV** (page 239)-positive received either *Lactobacillus acidophilus* vaginal suppositories, the antifungal drug, clotrimazole (e.g., Gyne-Lotrimin), or placebo weekly for 21 months.<sup>6</sup> Compared to those receiving placebo, women receiving *Lactobacillus acidophilus* suppositories had only half the risk of experiencing an episode of Candida vaginitis—a result almost as good as that achieved with clotrimazole.

Many women find relief using an acidophilus-containing yogurt douche daily for a few days or weeks, depending on the severity of the infection.<sup>7</sup> Three capsules of acidophilus or one-quarter teaspoon of powder can be taken orally one to three times daily. Acidophilus can also be taken preventively during antibiotic use to reduce the risk of Candida vaginitis.<sup>8,9</sup>

**Boric acid** (page 476) capsules inserted in the vagina have been used successfully as a treatment for vaginal yeast infections. One study demonstrated that 85% of women who used boric acid vaginal suppositories were cured of chronic recurring yeast vaginitis.<sup>10</sup> These women had all previously failed to respond to treatment with conventional antifungal medicines. The suppositories, which contained 600 mg of boric acid, were inserted vaginally twice a day for two weeks, then continued for an additional two weeks if necessary. Boric acid should never be swallowed.

*Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

**Herbs that may be helpful**

A small, preliminary trial found that a mouthwash with diluted **tea tree oil** (page 751) was effective in decreasing the growth of *Candida albicans* and in improving symptoms in **AIDS** (page 239) patients with oral *Candida* infections (thrush) that had not responded to drug therapy.<sup>11</sup> People in the study took 15 ml of the oral solution (dilution of tea tree oil was not given) four times per day and were instructed to swish it in their mouth for 30 to 60 seconds and then spit it out. For use of tea tree oil as a mouthwash, one should not exceed a 5% dilution and should be extremely careful not to swallow the solution.

Many doctors recommend that people with recurrent yeast infections take measures to support their **immune system** (page 255). **Echinacea** (page 669), which has the capacity to enhance immune function, is often used by people who suffer from recurrent **infections** (page 265). In one study, women who took echinacea experienced a 43% decline in the recurrence rate of yeast infections.<sup>12</sup>

The essential oil of **cinnamon** (page 659) contains various chemicals that are believed to be responsible for cinnamon's medicinal effects. Important among these compounds are eugenol and cinnamaldehyde. Cinnamaldehyde and cinnamon oil vapors exhibit extremely potent antifungal properties in test tubes.<sup>13</sup> In a preliminary study in people with **AIDS** (page 239), topical application of cinnamon oil was effective against oral thrush.<sup>14</sup>

A test tube study demonstrated that oil of **oregano** (page 719), and an extract in the oil called carvacrol in particular, inhibited the growth of *Candida albicans* far more effectively than a commonly employed antifungal agent called calcium magnesium caprylate.<sup>15</sup> However, clinical studies are needed to confirm these actions in humans.

*Are there any side effects or interactions?*

Refer to the individual herb for information about any side effects or interactions.

## YELLOW NAIL SYNDROME

Yellow nail syndrome is believed to be caused by congenital abnormalities in the lymphatic system.

Although it primarily affects the nails and lymphatic tissue, it frequently is associated with lung disease.

### CHECKLIST FOR YELLOW NAIL SYNDROME

Rating	Nutritional Supplements	Herbs
★★☆	Vitamin E (page 609)	

**What are the symptoms of yellow nail syndrome?**

People with yellow nail syndrome may have symptoms including thickened, curved, slow-growing, yellow-to-greenish nails; and swelling of the lymph system in various parts of the body. Additional symptoms relating to the lungs may also occur.

**Medical treatments**

Prescription drug therapy might include oral antibiotics to control infection in the airway, such as amoxicillin/clavulanate (Augmentin), cephalexin (Keflex), clarithromycin (Biaxin), and azithromycin (Zithromax). Bronchodilators, such as albuterol (Proventil, Ventolin), salmeterol (Serevent), and ipratropium bromide (Atrovent), may be used to open airways.

Treatment may include physical therapy, such as postural drainage, clapping, and vibration. Healthcare practitioners typically recommend avoiding cigarette smoke and other respiratory irritants, cough suppressants, and sleeping pills.

**Nutritional supplements that may be helpful**

Supplementation with **vitamin E** (page 609) has been used successfully with people who have yellow nail syndrome in several preliminary reports.<sup>1, 2, 3</sup> Although topical use of the vitamin has also been reported to be effective,<sup>4</sup> taking vitamin E supplements is much easier and less messy. A typical amount is 800 IU per day, with results beginning to appear after several months.

*Are there any side effects or interactions?*

Refer to the individual supplement for information about any side effects or interactions.

P A R T   T W O

## **Nutritional Supplements**

## 5-HYDROXYTRYPTOPHAN

### What is it?

5-HTP is used by the human body to make serotonin, an important substance for normal nerve and brain function. Serotonin appears to play significant roles in sleep, emotional moods, pain control, inflammation, intestinal peristalsis, and other body functions.<sup>1</sup>

### Where is it found?

5-HTP is not present in significant amounts in a typical diet. The human body manufactures 5-HTP from L-tryptophan, a natural **amino acid** (page 465) found in most dietary proteins. However, eating food that contains L-tryptophan does not significantly increase 5-HTP levels. Supplemental 5-HTP is naturally derived from the seeds of *Griffonia simplicifolia*, a West African medicinal plant.

### 5-HTP has been used in connection with the following conditions

(refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Depression</b> (page 145) <b>Fibromyalgia</b> (page 191) <b>Insomnia</b> (page 270) <b>Migraine headaches</b> (page 316) Sleep terrors <b>Tension headache</b> (page 428) <b>Weight loss and obesity</b> (page 446)
★★★	<b>Bipolar disorder/manic depression</b> (page 61) <b>Eating disorders</b> (page 174) <b>Parkinson's disease</b> (page 345) (with Sinemet) <b>Seasonal affective disorder</b> (page 397)

### Who is likely to be deficient?

Disruptions in emotional well-being, including **depression** (page 145) and **anxiety** (page 30), have been linked to serotonin imbalances in the brain.<sup>2</sup> People with **fibromyalgia** (page 191) often have low serotonin levels in their blood.<sup>3, 4, 5</sup> Supplements of 5-HTP may increase serotonin synthesis in these cases. The cause of **migraine headaches** (page 316) is related to abnormal serotonin function in blood vessels,<sup>6</sup> and 5-HTP may help correct this abnormality. **Insomnia** (page 270) has been associated with tryptophan deficiency in the tissues of the brain;<sup>7</sup> therefore, 5-HTP may provide a remedy for this condition.

### How much is usually taken?

In a controlled trial, 5-HTP (300 mg per day) was shown to be effective in reducing many symptoms of **fibromyalgia** (page 191), including **pain** (page 338), morning stiffness, sleep disturbances, and **anxiety** (page 30).<sup>8</sup>

For **depression** (page 145), 300 mg per day is often effective, though much of the research used 5-HTP in combination with drugs or was uncontrolled.<sup>9, 10, 11</sup> For **insomnia** (page 270), a single 100-mg nighttime dose of 5-HTP was sufficient to improve the duration and depth of sleep in one placebo-controlled trial.<sup>12</sup> For **migraine headaches** (page 316), amounts ranging from 400–600 mg per day have been shown to be effective at reducing the frequency and severity of attacks in most clinical trials.<sup>13, 14, 15, 16, 17</sup> For **tension headaches** (page 428), 100 mg of 5-HTP taken three times per day led to a significant decrease in consumption of pain-relievers, but no significant change in headache duration or intensity.<sup>18</sup>

Appetite reduction and **weight loss** (page 446) (averaging 11 pounds in 12 weeks) has occurred with

amounts of 600–900 mg daily.<sup>19, 20</sup> In another clinical trial, 750 mg per day has been shown to be effective at decreasing carbohydrate and fat intake, and promoting weight loss.<sup>21</sup>

#### **Are there any side effects or interactions?**

During the clinical trials described above, some people taking large amounts of 5-HTP experienced gastrointestinal upset (e.g. nausea) or, less often, headache, sleepiness, muscle pain, or **anxiety** (page 30).

A substance known as “Peak X” has been found in low concentrations in several over-the-counter 5-HTP preparations. Some researchers think this substance may be linked<sup>22, 23, 24</sup> to toxicity previously reported<sup>25, 26, 27</sup> in a 1989 L-tryptophan contamination incident. However, there is serious question about whether Peak X is actually the toxic agent and it may be unrelated to the problems previously associated with L-tryptophan.<sup>28, 29, 30, 31, 32, 33, 34, 35</sup> Although two articles reported possible associations between 5-HTP consumption and toxicity symptoms similar to those attributed to contaminated L-tryptophan,<sup>36, 37</sup> evidence linking 5-HTP or Peak X with any toxicity symptoms remains speculative. Although the structure of Peak X has recently been identified, there is no firm evidence that this substance has caused or contributed to any toxicity or disease.<sup>38</sup>

Very high intakes of 5-HTP have caused muscle jerks in guinea pigs<sup>39</sup> and both muscle jerks<sup>40</sup> and diarrhea in mice.<sup>41</sup> Injected 5-HTP has also caused kidney damage in rats.<sup>42</sup> To date, these problems have not been reported in humans. “Serotonin syndrome,” a serious but uncommon condition caused by excessive amounts of serotonin, has not been reported to result from supplementation with 5-HTP; in theory it could be triggered by the supplement.<sup>43</sup> However, the level of intake at which this toxic effect might potentially occur remains unknown.

5-HTP should not be taken with antidepressants, weight-control drugs, other serotonin-modifying agents, or substances known to cause liver damage, because in these cases 5-HTP may have excessive effects. People with liver disease may not be able to regulate 5-HTP adequately and those suffering from autoimmune diseases such as scleroderma may be more sensitive than others, to 5-HTP.<sup>44</sup> These people should not take 5-HTP without consulting a knowledgeable healthcare professional. The safety of taking 5-HTP during **pregnancy** (page 363) and breast-feeding is not known at this time.

## **7-KETO**

#### **What is it?**

7-KETO (3-acetyl-7-oxo-dehydroepiandrosterone) is a naturally occurring metabolite (breakdown product) of the hormone dehydroepiandrosterone (**DHEA** [page 503]).<sup>1</sup> DHEA is the most abundant of the adrenal steroid hormones and serves as a precursor for sex hormones, such as estrogen and testosterone.

7-KETO was developed by researchers who were looking for biologically active metabolites of DHEA that could not be converted to the potentially cancer-causing sex steroids (e.g., estrogen and testosterone).

Tests in animals and test tubes were performed in the areas of immune modulation, memory enhancement, and thermogenesis (the process the body uses to convert stored calories into energy). In all cases, the effects of 7-KETO were stronger than those produced by DHEA.<sup>2, 3, 4, 5</sup>

The capacity of 7-KETO to promote **weight loss** (page 446) in overweight people been investigated in a double-blind study.<sup>6</sup> Participants in the study were advised to exercise three times per week for 45 minutes and to eat an 1,800-calorie per day diet. Each person was given either a placebo or 100 mg of 7-KETO twice daily. After eight weeks, those receiving 7-KETO had lost an average of 6.34 pounds, compared with 2.13 pounds in the placebo group (a statistically significant difference). In addition, the percentage of body fat decreased by 1.8% in the 7-KETO group, compared with only 0.57% in the placebo group. The increased weight loss in the 7-KETO group was associated with a significant increase in levels of T3 (a thyroid hormone that plays a major role in determining a person’s metabolic rate), although the levels of T3 did not exceed the normal range.

#### **Where is it found?**

7-KETO is available as a dietary supplement.

**7-KETO has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Weight loss</b> (page 446)

**Who is likely to be deficient?**

Since the level of 7-KETO is directly related to the level of **DHEA** (page 503) in the body,<sup>7</sup> people with lower DHEA levels likely have low 7-KETO levels as well. Low DHEA levels are primarily associated with aging.

**How much is usually taken?**

The manufacturer of 7-KETO recommends 100 mg twice daily for **weight loss** (page 446).

**Are there any side effects or interactions?**

A safety study in humans has shown that 7-KETO did not raise estrogen or testosterone levels or produce any other negative effects at levels up to 200 mg per day for eight weeks.<sup>8</sup> Short-term animal studies also revealed no adverse effects with large amounts of 7-KETO.<sup>9, 10, 11</sup>

However, the long-term safety of 7-KETO for humans has not been demonstrated, and, because it is chemically related to steroid hormones, the potential for adverse effects must be considered. In addition, the increase in T3 levels resulting from taking 7-KETO could, in theory, produce adverse effects on the heart or promote bone loss. For these reasons, people wishing to take 7-KETO, particularly those who have a thyroid disorder or are taking thyroid hormone, should consult a physician.

## ACETYL-L-CARNITINE

**What is it?**

Acetyl-L-carnitine is similar in form to the amino acid **L-carnitine** (page 543) and also has some similar functions, such as being involved in the metabolism of food into energy. The acetyl group that is part of acetyl-L-carnitine contributes to the production of the neurotransmitter acetylcholine, which is required for mental function.

**Where is it found?**

Acetyl-L-carnitine is a molecule that occurs naturally in the brain, liver, and kidney. It is also available as a dietary supplement.

**Acetyl-L-carnitine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Age-related cognitive decline</b> (page 8)

★★★ **Alzheimer's disease** (page 19)  
Cerebellar ataxia, degenerative  
**Depression** (page 145) (for elderly people)  
Type 1 diabetes  
**Type 2 diabetes** (page 152)  
**Down's syndrome** (page 169)

★☆☆ **Amenorrhea** (page 22)  
**Male infertility** (page 305)  
Peripheral neuropathy

**Who is likely to be deficient?**

Acetyl-L-carnitine levels may decrease with advancing age. However, because it is not an essential nutrient, true deficiencies do not occur.

**How much is usually taken?**

Most research involving acetyl-L-carnitine has used 500 mg three times per day, though some research has used double this amount.<sup>1</sup>

**Are there any side effects or interactions?**

Side effects from taking acetyl-L-carnitine are uncommon, although skin rash, increased appetite, nausea, vomiting, agitation, and body odor have been reported in people taking acetyl-L-carnitine.<sup>2, 3</sup>

## ADENOSINE MONOPHOSPHATE

**What is it?**

Adenosine monophosphate (AMP) is an intermediary substance formed during the body's process of creating energy in the form of adenosine triphosphate (ATP) from food.

AMP may play a role in limiting postherpetic neuralgia, which is the pain that sometimes lingers after a bout of **shingles** (page 401) (herpes zoster). One double-blind study involving 32 adults with shingles found that injections of AMP given three times per week for a month following a flare-up of shingles relieved the pain more quickly than placebo.<sup>1</sup> Whether oral supplementation would have the same effect remains unclear. AMP also helps heal the lesions and prevents recurrence of pain or lesions.

Nineteen out of twenty-one people with porphyria cutanea tarda (a disease that develops in adulthood and causes **photosensitivity** (page 356), among other

symptoms) responded well to 160–200 mg of AMP per day taken for at least one month, according to one group of researchers.<sup>2</sup> Partial and even complete alleviation of photosensitivity associated with this condition occurred in several people.

A closely related molecule to AMP, adenosine, affects electrical signaling in the heart. Intravenous adenosine has been used successfully to treat children with tachycardia, a condition in which the heart beats too quickly.<sup>3</sup> Intravenous adenosine has also been reported to help most elderly people with tachycardia.<sup>4</sup>

Adenosine is formed by heart muscle when the oxygen supply is low,<sup>5</sup> and it improves the efficiency of the heart.<sup>6</sup> Adenosine has also been reported to improve the heart's ability to use blood sugar for energy during stress.<sup>7</sup>

#### Where is it found?

The body creates AMP within cells during normal metabolic processes. AMP is also found as a supplement, although it is not widely available.

**Adenosine monophosphate (AMP) has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Photosensitivity</b> (page 356) <b>Shingles</b> (page 401)

#### Who is likely to be deficient?

Preliminary research suggests that people with herpes simplex or herpes zoster (**shingles** [page 401]) infections may have low levels of AMP; however, the clinical significance of this finding is unclear.<sup>8</sup>

#### How much is usually taken?

The trials using AMP for **photosensitivity** (page 356) have used 160–200 mg of AMP per day; however, the ideal intake of this supplement has not been determined. Research with **shingles** (page 401) has used a special gel form of AMP injected into muscle; a doctor should be consulted for this form of AMP.

#### Are there any side effects or interactions?

The limited number of human studies involving oral AMP have not indicated any side effects. However, some researchers have expressed concern that supple-

mental intake of AMP could, in theory, increase levels of adenosine, a substance related to AMP that may interfere with **immune function** (page 255).<sup>9</sup> Doctors using AMP injections report that too-rapid intravenous administration or inadvertent administration of an intramuscular injection into a vein could cause life-threatening arrhythmias of the heart.<sup>10</sup>

## ADRENAL EXTRACT

#### What is it?

Adrenal extracts are derived from the adrenal glands of bovine (beef) sources. Commercially available adrenal extracts are made using the whole gland (whole or total adrenal extracts) or just the cortex or outer portion of the gland (adrenal cortex extracts). The adrenal glands are a pair of small glands that lie just above the kidneys.

The possible benefits of adrenal extract are thought to be the result of a combination of supplying small amounts of adrenal hormones and promoting improved adrenal function. The adrenal medulla secretes the hormones epinephrine (adrenaline) and norepinephrine (noradrenaline), while the adrenal cortex secretes an entirely different group of hormones called corticosteroids. Although all corticosteroids have similar chemical formulas, they differ in function. The three major types of corticosteroids are mineralocorticoids (e.g., aldosterone), glucocorticoids (cortisol or cortisone), and 17-ketosteroids (e.g., dehydroepiandrosterone [**DHEA** (page 503)]).

Adrenal extracts have been used in modern medicine since 1931, primarily in the injectable form along with **vitamin B<sub>6</sub>** (page 600), **vitamin B<sub>12</sub>** (page 601), or **vitamin C** (page 604). Although there is little in the area of scientific documentation for oral administration, a series of animal studies demonstrated that oral administration of adrenal extract to mice, rats, and dogs who had their adrenal glands removed produced the same activity as injectable adrenal extract.<sup>1, 2, 3</sup>

Whole adrenal extracts (usually in combination with essential nutrients required for proper adrenal function) are most often used in cases of low adrenal function presenting as fatigue, inability to cope with stress, and reduced resistance to infection. Because extracts made from the adrenal cortex contain small amounts of corticosteroids, they are typically used as “natural” cortisone in cases of **allergy** (page 14) and inflammation (**asthma** [page 32], **eczema** [page 177], **psoriasis**

[page 379], **rheumatoid arthritis** [page 387], etc.). The effectiveness of adrenal extracts in these applications is unknown at this time. People taking prescribed corticosteroids should never substitute these drugs with an adrenal extract and should consult their physician before adding an adrenal extract to their steroid treatment.

In a preliminary study done in the 1930s, 8 women suffering from nausea and vomiting during the first trimester of **pregnancy** (page 363) received large amounts of oral adrenal cortex extract. In most cases, vomiting stopped after 3 to 4 days.<sup>4</sup> In a follow-up study, 202 women with nausea and vomiting due to pregnancy received adrenal cortex extract, usually by injection at first, followed by oral administration. More than 85% of the women were completely relieved of the problem or showed definite improvement.<sup>5</sup>

#### Where is it found?

Adrenal extracts are available in capsules or tablets. Adrenal extracts prepared for injection were commonly used at one time, but currently are unavailable.

**Adrenal extract has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Fatigue <b>Morning sickness</b> (page 320)

#### Who is likely to be deficient?

As adrenal extract is not an essential nutrient, no nutritional deficiency state exists. However, some people sub-optimal adrenal function or frank adrenal insufficiency. The diagnosis of adrenal problems should be made by a physician.

#### How much is usually taken?

The amount of adrenal extract taken will depend upon the quality and potency of the product. Follow the recommendations given on the product label or those given by your healthcare provider.

#### Are there any side effects or interactions?

Stomach irritation and/or nausea is a common side effect, especially with higher potency products. Other possible side effects include a general stimulatory effect

that may manifest as **anxiety** (page 30), irritability, and/or **insomnia** (page 270). Since no safety data exist for use during **pregnancy** (page 363) or breast-feeding, adrenal extract should not be used in these situations unless supervised by a doctor.

Consumption of excessive amounts may produce signs and symptoms of corticosteroid excess similar to those experienced with the drug prednisone. However, serious side effects are not likely to result from taking a large amount of an adrenal extract for a short period of time or from excessive intake on a single occasion, but rather from long-term use of high amounts. With prednisone (a synthetic cortisone-like drug) at lower doses (less than 10 mg per day), the most notable side effects are usually increased appetite, weight gain, retention of salt and water, and increased susceptibility to **infection** (page 265).

## ALANINE

#### What is it?

Alanine is a nonessential **amino acid** (page 465) used by the body to build proteins.

Alanine is present in prostate fluid, and it may play a role in supporting prostate health. One study, involving 45 men with benign prostatic hyperplasia (**BPH** [page 58]), found that 780 mg of alanine per day for two weeks and then 390 mg for the next two and a half months, taken in combination with equal amounts of the amino acids **glycine** (page 532) and **glutamic acid** (page 529), reduced symptoms of BPH;<sup>1</sup> this work has been independently confirmed.<sup>2</sup>

#### Where is it found?

As with the other **amino acids** (page 465), excellent sources of alanine include meat and poultry, fish, eggs, and dairy products. Some protein-rich plant foods also supply alanine.

**Alanine has been used in connection with the following condition** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Benign prostatic hyperplasia</b> (page 58) (in combination with glycine and glutamic acid)

### Who is likely to be deficient?

Since alanine is synthesized in the body and is also provided by most foods that are sources of protein, deficiencies are unlikely to occur.<sup>3</sup>

### How much is usually taken?

Most people do not need to supplement with alanine; for those who do use this **amino acid** (page 465) as a supplement, appropriate amounts should be determined with the consultation of a physician.

### Are there any side effects or interactions?

Alanine is free of side effects for the vast majority of people who take it; however, people with kidney or liver disease should not consume high intakes of **amino acids** (page 465) without consulting a healthcare professional.

## ALPHA LIPOIC ACID

### What is it?

Alpha lipoic acid (ALA) is a vitamin-like **antioxidant** (page 467), sometimes referred to as the “universal antioxidant” because it is soluble in both fat and water.<sup>1</sup> ALA is manufactured in the body and is found in some foods, particularly liver and yeast.

ALA is capable of regenerating several other antioxidants back to their active states, including **vitamin C** (page 604),<sup>2</sup> **vitamin E** (page 609),<sup>3</sup> **glutathione** (page 531),<sup>4</sup> and **coenzyme Q<sub>10</sub>** (page 496).<sup>5</sup>

ALA has several potential benefits for people with diabetes. It enhances glucose uptake in type 2 (adult onset or non-insulin-dependent) **diabetes** (page 152), inhibits glycosylation (the abnormal attachment of sugar to protein), and has been used to improve diabetic nerve damage and reduce pain associated with that nerve damage.<sup>6</sup> Most studies have used intravenous alpha lipoic acid, but oral supplementation has nonetheless proved partially helpful in treating at least one form of diabetic neuropathy, using 800 mg per day.<sup>7</sup>

Preliminary evidence indicates that 150 mg of alpha lipoic acid, taken daily for one month, improves visual function in people with **glaucoma** (page 205).<sup>8</sup>

ALA has been shown to inhibit the replication of the **HIV** (page 239) virus in the test tube; however, it is not known whether supplementing with ALA would benefit HIV-infected people.<sup>9</sup>

Intravenous administration of ALA has significantly increased the survival rate of people who have eaten poisonous mushrooms.<sup>10</sup> Such a treatment should be prescribed by a doctor and should not be attempted on one's own.

### Where is it found?

The body makes small amounts of alpha lipoic acid. There is only limited knowledge about the food sources of this nutrient. However, foods that contain mitochondria (a specialized component of cells), such as red meats, are believed to provide the most alpha lipoic acid. Supplements are also available.

**Alpha lipoic acid has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★	<b>Diabetes</b> (page 152)
★★★	<b>Glaucoma</b> (page 205) <b>Hepatitis</b> (page 220)

### Who is likely to be deficient?

Although alpha lipoic acid was thought to be a vitamin when it was first discovered, subsequent research determined that it is created in the human body—and thus is not an essential nutrient. For this reason, deficiencies of alpha lipoic acid are not known to occur in humans.

### How much is usually taken?

The amount of alpha lipoic acid used in research to improve diabetic neuropathies is 800 mg per day and 150 mg per day for **glaucoma** (page 205). However, much lower amounts, such as 20–50 mg per day, are recommended by some doctors for general **antioxidant** (page 467) protection, although there is no clear evidence that such general use has any benefit.

### Are there any side effects or interactions?

Side effects with alpha lipoic acid are rare but can include skin rash and the potential of **hypoglycemia** (page 251) in diabetic patients. People who may be deficient in **vitamin B<sub>1</sub>** (page 597) (such as alcoholics) should take vitamin B<sub>1</sub> along with alpha lipoic acid supplements. Chronic administration of alpha lipoic acid in animals has interfered with the actions of the vi-

tamin, **biotin** (page 473). Whether this has significance for humans remains unknown.<sup>11</sup>

## AMINO ACIDS OVERVIEW

### What are they?

Amino acids are the building blocks of protein. Twenty amino acids are needed to build the various proteins used in the growth, repair, and maintenance of body tissues. Eleven of these amino acids can be made by the body itself, while the other nine (called essential amino acids) must come from the diet. The essential amino acids are **isoleucine** (page 479), **leucine** (page 479), **lysine** (page 550), **methionine** (page 557), **phenylalanine** (page 568), threonine, tryptophan, and **valine** (page 479). Another amino acid, **histidine** (page 534), is considered semi-essential because the body does not always require dietary sources of it. The nonessential amino acids are **arginine** (page 467), **alanine** (page 463), asparagine, aspartic acid, **cysteine** (page 502), **glutamine** (page 530), **glutamic acid** (page 529), **glycine** (page 532), proline, serine, and **tyrosine** (page 544). Other amino acids, such as carnitine, are used by the body in ways other than protein-building and are often used therapeutically.

The classification of an amino acid as essential or nonessential does not reflect its importance, because all 20 amino acids are necessary for health. Instead, this classification system simply reflects whether or not the body is capable of manufacturing a particular amino acid.

### Where are they found?

Foods of animal origin, such as meat and poultry, fish, eggs, and dairy products, are the richest dietary sources of the essential amino acids. Plant sources of protein are often deficient in one or more essential amino acids. However, these deficiencies can be overcome by consuming a wide variety of plant foods. For example, grains are low in **lysine** (page 550), whereas beans provide an excess of lysine. It was previously believed that, in order for vegetarians to obtain adequate amounts of protein, all of the essential amino acids had to be “balanced” at each meal. For example, a grain and a bean had to be consumed at the same meal. However, more recent research has indicated that, while consuming a proper mix of amino acids is important, it is not necessary to consume them all at the same meal.<sup>1</sup>

**Amino acids have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Angina</b> (page 27) ( <b>carnitine</b> [page 543]) <b>Bronchitis</b> (page 80) ( <b>N-acetyl cysteine</b> [page 562]) <b>Chronic obstructive pulmonary disease</b> (page 114) ( <b>N-acetyl cysteine</b> [page 562]) <b>Cold sores</b> (page 119) ( <b>lysine</b> [page 550]) <b>Congestive heart failure</b> (page 134) ( <b>propionyl-L-carnitine</b> [page 543], <b>taurine</b> [page 590])
★★☆	<b>Alzheimer's disease</b> (page 19) ( <b>acetyl-L-carnitine</b> [page 461]) <b>Angina</b> (page 27) ( <b>arginine</b> [page 467]) <b>Athletic performance</b> (page 43) ( <b>creatine</b> [page 501]) <b>Benign prostatic hyperplasia</b> (page 58) ( <b>alanine</b> [page 463], <b>glutamic acid</b> [page 529], <b>glycine</b> [page 532]) <b>Chronic fatigue syndrome</b> (page 111) ( <b>carnitine</b> [page 543]) <b>Congestive heart failure</b> (page 134) ( <b>arginine</b> [page 467]) <b>Depression</b> (page 145) ( <b>5-HTP</b> [page 459], <b>DLPA</b> [page 568], <b>L-phenylalanine</b> [page 568], <b>tyrosine</b> [page 544]) <b>Diabetes</b> (page 152) ( <b>carnitine</b> [page 543]) <b>Fibromyalgia</b> (page 191) ( <b>5-HTP</b> [page 459]) <b>High triglycerides</b> (page 235) ( <b>carnitine</b> [page 543]) <b>HIV support</b> (page 239) ( <b>N-acetyl cysteine</b> [page 562]) <b>Infertility (male)</b> (page 305) ( <b>arginine</b> [page 467], <b>carnitine</b> [page 543]) <b>Insomnia</b> (page 270) ( <b>5-HTP</b> [page 459]) <b>Intermittent claudication</b> (page 276) ( <b>carnitine</b> [page 543]) <b>Liver support</b> ( <b>taurine</b> [page 590]) <b>Migraine headaches</b> (page 316) ( <b>5-HTP</b> [page 459]) <b>Pain</b> (page 338) ( <b>DPA</b> [page 568]) <b>Phenylketonuria</b> (page 354) ( <b>tyrosine</b> [page 544]) <b>Vitiligo</b> (page 443) ( <b>L-phenylalanine</b> [page 568]) <b>Weight loss and obesity</b> (page 446) ( <b>5-HTP</b> [page 459])

Rating	Health Concerns
★☆☆	<b>Alcohol withdrawal</b> (page 12) ( <b>DLPA</b> [page 568], <b>glutamine</b> [page 530], <b>tyrosine</b> [page 544]) <b>Athletic performance</b> (page 43) ( <b>arginine</b> [page 467]/ <b>ornithine</b> [page 565], <b>carnitine</b> [page 543]) <b>Diabetes</b> (page 152) ( <b>taurine</b> [page 590]) <b>Epilepsy</b> (page 183) ( <b>taurine</b> [page 590]) <b>High blood pressure</b> (page 246) ( <b>arginine</b> [page 467], <b>taurine</b> [page 590]) <b>HIV support</b> (page 239) ( <b>glutamine</b> [page 530], <b>methionine</b> [page 557]) <b>Liver support</b> ( <b>methionine</b> [page 557]) <b>Osteoarthritis</b> (page 328) ( <b>DPA</b> [page 568]) <b>Peptic ulcer</b> (page 349) ( <b>glutamine</b> [page 530]) <b>Rheumatoid arthritis</b> (page 387) ( <b>DPA</b> [page 568])

### Who is likely to be deficient?

The vast majority of Americans eat more than enough protein and also more than enough of each essential amino acid for normal purposes. Dieters, some strict vegetarian body builders, and anyone consuming an inadequate number of calories may not be consuming adequate amounts of amino acids. In these cases, the body will break down the protein in muscle tissue and use those amino acids to meet the needs of more important organs or will simply not build more muscle mass despite increasing exercise.

### How much is usually taken?

Nutrition experts recommend that protein, as a source of amino acids, should account for 10–12% of the calories in a balanced diet. However, requirements for protein are affected by age, weight, state of health, and other factors. On average, a normal adult requires approximately 0.36 grams of protein per pound of body weight. Using this formula, a 140-pound person would need 50 grams (or less than 2 ounces) of protein per day. An appropriate range of protein intake for healthy adults may be as low as 45–65 grams daily. Some athletes have higher amino acid requirements.<sup>2</sup> Most American adults eat about 100 grams of protein per day, or about twice what their bodies need and at least as much as any athlete requires.

Supplements of individual amino acids are recommended by doctors for specific purposes, such as **lysine**

(page 550) for **herpes** (page 200) or **phenylalanine** (page 568) for **pain** (page 238).

### Are there any side effects or interactions?

Most diets provide more protein than the body needs, causing excess nitrogen to be excreted as urea in urine. The excess nitrogen has been linked in some studies with reduced kidney function in old age. Most, but not all studies have found that when people have impaired kidney function, restricting dietary intake of protein slows the rate of decline of kidney function.<sup>3</sup>

Excessive protein intake also can increase excretion of **calcium** (page 483), and some evidence has linked high-protein diets with **osteoporosis** (page 333),<sup>4</sup> particularly regarding animal protein.<sup>5</sup> On the other hand, some protein is needed for bone formation. A double-blind study showed that elderly people whose diets provided slightly less than the recommended amount of protein suffered less bone loss if they consumed an additional 20 grams of protein per day.<sup>6</sup> A doctor can help people assess their protein intake.

## AMYLASE INHIBITORS

### What are they?

Amylase inhibitors are also known as starch blockers because they contain substances that prevent dietary starches from being absorbed by the body. Starches are complex carbohydrates that cannot be absorbed unless they are first broken down by the digestive enzyme amylase and other, secondary, enzymes.<sup>1, 2</sup> They are claimed to be useful for **weight loss** (page 446), but when they were first developed years ago, research did not find them very effective for limiting carbohydrate absorption.<sup>3, 4, 5, 6</sup> Later, however, highly concentrated versions of amylase inhibitors did show potential for reducing carbohydrate absorption in humans.<sup>7, 8, 9</sup>

Purified starch blocker extracts, when given with a starchy meal, have also been shown to reduce the subsequent rise in blood sugar levels of both healthy people and **diabetics** (page 152).<sup>10, 11, 12, 13</sup> This effect could be helpful in the treatment of blood sugar disorders.

### Where are they found?

Amylase inhibitors can be extracted from several types of plants, especially those in the legume family. Currently available Amylase inhibitors are extracted from either white kidney bean or wheat.

**Amylase inhibitors have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Diabetes</b> (page 152) <b>Weight loss and obesity</b> (page 446)

### Who is likely to be deficient?

Amylase inhibitors are not essential nutrients and are not normally produced in the body, so no deficiency is possible.

### How much is usually taken?

Depending on the potency of the amylase inhibitors, typical intake is 1,500 to 6,000 mg before meals.

### Are there any side effects or interactions?

High amounts of amylase inhibitors may cause **diarrhea** (page 163) due to the effects of undigested starch in the colon.<sup>14, 15</sup> Diabetics taking medications to lower their blood sugar should not take amylase inhibitors without first consulting a doctor.

## ANTIOXIDANTS AND FREE RADICALS

Free radicals are highly reactive compounds that are created in the body during normal metabolic functions or introduced from the environment. Free radicals are inherently unstable, since they contain “extra” energy. To reduce their energy load, free radicals react with certain chemicals in the body, and in the process, interfere with the cells’ ability to function normally. Antioxidants work in several ways: they may reduce the energy of the free radical, stop the free radical from forming in the first place, or interrupt an oxidizing chain reaction to minimize the damage caused by free radicals.

Free radicals are believed to play a role in more than sixty different health conditions, including the aging process, **cancer** (page 87), and **atherosclerosis** (page 38).<sup>1</sup> Reducing exposure to free radicals and increasing intake of antioxidant nutrients has the potential to reduce the risk of free radical-related health problems.

Oxygen, although essential to life, is the source of the potentially damaging free radicals. Free radicals are also found in the environment. Environmental sources of free radicals include exposure to ionizing radiation (from industry, sun exposure, cosmic rays, and medical X-rays), ozone and nitrous oxide (primarily from automobile exhaust), heavy metals (such as mercury, cadmium, and lead), cigarette smoke (both active and passive), alcohol, unsaturated fat, and other chemicals and compounds from food, water, and air.

The body produces several antioxidant enzymes, including superoxide dismutase (SOD), catalase, and glutathione peroxidase, that neutralize many types of free radicals. Supplements of these enzymes are available for oral administration. However, their absorption is probably minimal at best. Supplementing with the “building blocks” the body requires to make SOD, catalase, and glutathione peroxidase may be more effective. These building block nutrients include the minerals **manganese** (page 553), **zinc** (page 614), and **copper** (page 499) for SOD and **selenium** (page 584) for glutathione peroxidase.

In addition to enzymes, many vitamins and minerals act as antioxidants in their own right, such as **vitamin C** (page 604), **vitamin E** (page 609), **beta-carotene** (page 469), **lutein** (page 548), **lycopene** (page 548), **vitamin B<sub>2</sub>** (page 598), **coenzyme Q<sub>10</sub>** (page 496), and **cysteine** (page 502) (an amino acid). Herbs, such as **bilberry** (page 634), **turmeric** (page 753) (curcumin), grape seed or pine bark extracts, and **ginkgo** (page 681) can also provide powerful antioxidant protection for the body.

Consuming a wide variety of antioxidant enzymes, vitamins, minerals, and herbs may be the best way to provide the body with the most complete protection against free radical damage.

## ARGININE

### What is it?

The **amino acid** (page 465) arginine has several roles in the body, such as assisting in **wound healing** (page 319), helping remove excess ammonia from the body, stimulating **immune function** (page 255), and promoting secretion of several hormones, including glucagon, insulin, and growth hormone.

The effect of arginine on growth hormone levels<sup>1</sup> has interested body builders. In a controlled trial, when arginine and **ornithine** (page 565) (500 mg of each, twice per day, five times per week) were combined with weight training, a greater decrease in body fat was obtained after only five weeks than when the same exercise was combined with a placebo.<sup>2</sup> In another study, however, 5 grams of arginine powder, taken orally 30 minutes prior to exercise, failed to affect growth hormone release and may have even impaired the release of growth hormone in younger adults.<sup>3</sup>

Arginine is also needed to increase protein synthesis, which can in turn increase cellular replication. Therefore, arginine may help people with inadequate numbers of certain cells. For example, some,<sup>4</sup> though not all,<sup>5</sup> studies have found that men with low sperm counts experienced an increase in the number of sperm when they supplemented with arginine.

Arginine's effect on increasing protein synthesis improves **wound healing** (page 319). This effect has been shown in both animals<sup>6</sup> and people (at 17 grams per day).<sup>7</sup>

Arginine is also a precursor to nitric oxide, which the body uses to keep blood vessels dilated, allowing the heart to receive adequate oxygen. Researchers have begun to use arginine in people with **angina** (page 27) and **congestive heart failure** (page 134).

Nitric oxide metabolism is also altered in people with interstitial cystitis, a condition of the bladder. Preliminary research found that supplementation with 1.5 grams of arginine per day for six months led to a significant decrease in most symptoms, including pain,<sup>8</sup> though short-term supplementation (five weeks) has not been effective, even at higher intakes (3–10 grams per day).<sup>9</sup> In 1999, a double-blind study using 1.5 grams of arginine for three months in a group of women with interstitial cystitis, reported considerable improvement compared with the effect of a placebo in a variety of indices. Perhaps due to the small size of the study, some of these changes did not quite reach statistical significance.<sup>10</sup>

Preliminary evidence suggests that arginine may help regulate **cholesterol levels** (page 223).<sup>11</sup> Arginine also appears to act as a natural blood thinner by reducing platelet aggregation.<sup>12</sup>

#### Where is it found?

Dairy, meat and poultry, and fish are good sources of arginine. Nuts and chocolate also contain significant amounts of this **amino acid** (page 465).

**Arginine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Angina</b> (page 27) <b>Congestive heart failure</b> (page 134) <b>Erectile dysfunction</b> (page 185) <b>HIV support</b> (page 239) (in combination with glutamine [page 530] and <b>HMB</b> [page 534]) <b>Infertility (male)</b> (page 305) <b>Intermittent claudication</b> (page 276) (I.V. only) <b>Interstitial cystitis</b> <b>Pre- and post-surgery health</b> (page 357) <b>Sickle cell anemia</b> (page 403) (for pulmonary hypertension)
★☆☆	<b>Athletic performance</b> (page 43) (for body composition and strength) <b>Female infertility</b> (page 187) (for in vitro fertilization) <b>Gastritis</b> (page 195) <b>High blood pressure</b> (page 246) <b>Wound healing</b> (page 357)

#### Who is likely to be deficient?

Normally, the body makes enough arginine, even when it is lacking in the diet. However, during times of unusual stress (including **infection** [page 265], **burns** [page 85], and **injury** [page 319]), the body may not be able to keep up with increased requirements.

#### How much is usually taken?

Most people do not need to take extra arginine. While some people with serious **infections** (page 265), **burns** (page 85), or other trauma should take arginine, appropriate amounts must be determined by a doctor. Levels used in research vary considerably (2–30 grams per day). Most research on **cardiovascular disease** (page 98) has used between 6 and 20 grams per day. Optimal intakes remain unknown and are likely to vary depending upon the individual.

#### Are there any side effects or interactions?

Arginine has so far appeared to be free of obvious side effects. However, longer-term studies are needed to confirm its safety.

There have been two case reports of severe allergic reactions following intravenous administration of L-arginine;<sup>13</sup> however, allergic reactions have not been reported after oral administration.

People with kidney or liver disease should consult their doctor before supplementing with arginine. Some doctors believe that people with herpes (either **cold sores** [page 119] or **genital herpes** [page 200]) should not take arginine supplements, because of the possibility that arginine might stimulate replication of the virus.

Administration of large amounts of arginine to animals has been found both to promote<sup>14</sup> and to interfere with **cancer** (page 87) growth.<sup>15</sup> In preliminary research, high intake (30 grams per day) of arginine has increased cancer cell growth in humans.<sup>16</sup> On the other hand, in people with cancer, arginine has been found to stimulate the **immune system** (page 255).<sup>17</sup> At this time it remains unclear whether arginine is dangerous or helpful for people with cancer.

Arginine works with **ornithine** (page 565) in the synthesis of growth hormone.

## BETA-CAROTENE

### What is it?

Beta-carotene is a substance from plants that the body converts into **vitamin A** (page 595). It also acts as an **antioxidant** (page 467) and an **immune system** (page 255) booster.

Other members of the antioxidant carotenoid family include cryptoxanthin, alpha-carotene, zeaxanthin, **lutein** (page 548), and **lycopene** (page 548). However, unlike beta-carotene, most of these nutrients are not converted to vitamin A in significant amounts.

### Where is it found?

Dark green and orange-yellow vegetables are good sources of beta-carotene. It is also available in supplements.

**Beta-carotene has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Leukoplakia</b> (page 289) <b>Lung cancer</b> (page 298) ( <b>Warning:</b> Beta-carotene increases the risk of lung cancer in smokers.) <b>Night blindness</b> (page 326) <b>Photosensitivity</b> (page 356)

★★★	<b>Immune function</b> (page 255) <b>Pancreatic insufficiency</b> (page 341)
★☆☆	<b>Alcohol withdrawal support</b> (page 12) <b>Asthma</b> (page 32) <b>Cataracts</b> (page 101) <b>Gastritis</b> (page 195) <b>Heart attack</b> (page 212) <b>HIV support</b> (page 239) <b>Macular degeneration</b> (page 303) <b>Sickle cell anemia</b> (page 403)

### Who is likely to be deficient?

People who limit their consumption of beta-carotene-containing vegetables could be at higher risk of developing a **vitamin A** (page 595) deficiency. However, because beta-carotene is not an essential nutrient, true deficiencies do not occur. Nevertheless, very old persons with type 2 **diabetes** (page 152) have shown a significant age-related decline in blood levels of carotenoids, irrespective of their dietary intake.<sup>1</sup>

### Which form is best?

Most beta-carotene in supplements is synthetic, consisting of only one molecule called all trans beta-carotene. Natural beta-carotene, found in food, is made of two molecules—all trans beta-carotene and 9-cis beta-carotene.

Researchers originally saw no meaningful difference between natural and synthetic beta-carotene. This view was questioned when the link between beta-carotene-containing foods (all natural) and **lung cancer** (page 298) prevention<sup>2</sup> was not duplicated in studies using synthetic pills.<sup>3</sup> In smokers, synthetic beta-carotene has apparently caused an increased risk of lung cancer<sup>4, 5, 6</sup> and disease of the blood vessels<sup>7</sup> in double-blind research. Animal research has begun to identify the ways in which synthetic beta-carotene might cause damage to lungs, particularly when animals are exposed to cigarette smoke.<sup>8</sup>

Much of natural beta-carotene is in the all trans molecule form—the same as synthetic beta-carotene. Moreover, much of the 9-cis molecule found only in natural beta-carotene is converted to the synthetic molecule before it reaches the bloodstream.<sup>9</sup> Also, absorption of 9-cis beta-carotene appears to be poor,<sup>10</sup> though some researchers question this finding.<sup>11</sup>

Despite the overlap between natural and synthetic forms, natural beta-carotene may possibly have activity that is distinct from the synthetic form. For example, studies in both animals<sup>12</sup> and humans<sup>13</sup> have shown

that the natural form has **antioxidant** (page 467) activity that the synthetic form lacks. Also, in one trial, pre-cancerous changes in people reverted to normal tissue with natural beta-carotene supplements, but not with synthetic supplements.<sup>14</sup> Israeli researchers have investigated whether the special antioxidant effects of natural beta-carotene might help people suffering from **asthma** (page 32) attacks triggered by exercise.<sup>15</sup> People with asthma triggered by exercise were given 64 mg per day of natural beta-carotene for one week. In that report, 20 of 38 patients receiving natural beta-carotene were protected against exercise-induced asthma. However, because synthetic beta-carotene was not tested, the difference between the activity of the two supplements cannot be deduced from this report.

Increasingly, doctors are recommending that people supplement only with natural beta-carotene. However, no studies have explored whether the adverse effect of synthetic beta-carotene in cigarette smokers would also occur with *natural* beta-carotene supplementation. Until more is known, smokers should avoid all beta-carotene supplements and others should avoid synthetic beta-carotene.

In supplements, the natural form can be identified by the phrases “from *D. salina*,” “from an algal source,” “from a palm source,” or as “natural beta-carotene” on the label. The synthetic form is identified as “beta-carotene.”

#### **How much is usually taken?**

The most common beta-carotene supplement intake is probably 25,000 IU (15 mg) per day, though some people take as much as 100,000 IU (60 mg) per day. Whether the average person would benefit from supplementation with beta-carotene remains unclear.

#### **Are there any side effects or interactions?**

Beta-carotene supplementation, even in very large amounts, is not known to cause any serious side effects,<sup>16, 17</sup> however, excessive intake (more than 100,000 IU, or 60 mg per day) sometimes gives the skin a yellow-orange hue. People taking beta-carotene for long periods of time should also supplement with **vitamin E** (page 609), as beta-carotene may reduce vitamin E levels.<sup>18</sup> Beta carotene supplementation may also decrease blood levels of **lutein** (page 548), another carotenoid.<sup>19</sup>

**Warning:** Synthetic beta-carotene has now been linked to increased risk of **lung cancer** (page 298) in smokers. Until more is known, smokers should avoid all beta-carotene supplements.

Preliminary studies in animals indicate that beta-carotene supplementation, when combined with heavy **alcohol** (page 12) consumption, may enhance liver toxicity.<sup>20</sup> Until more is known, alcoholics and persons who consume alcohol on a daily basis should avoid supplementing with beta-carotene.

One study showed a slightly increased risk of vascular surgery among people with **intermittent claudication** (page 276) who took beta-carotene supplements.<sup>21</sup> Until more is known, persons wishing to use beta-carotene supplements should first consult with their doctor.

## **BETA-GLUCAN**

#### **What is it?**

Beta-glucan is a fiber-type complex sugar (polysaccharide) derived from the cell wall of baker's yeast, **oat** (page 716) and barley fiber, and many medicinal mushrooms, such as **maitake** (page 707). In their natural states, yeast and mushrooms contain a mixture of beta-1,3-glucan and beta-1,6-glucan. Oats and barley contain a mixture of beta-1,3-glucan and beta-1,4-glucan. In addition to purified beta-1,3-glucan from these sources, you may see products listed as beta-1,3/1,6-glucan in the case of yeast-derived products and as beta-1,3/1,4-glucan when derived from oats. Similar (if not identical) properties have been shown for beta-glucan-rich extracts and purified beta-glucan derived from oats, baker's yeast, and mushrooms.

The two primary uses of beta-glucan are to enhance the **immune system** (page 255) and to lower blood **cholesterol** (page 223) levels. Numerous experimental studies in test tubes and animals have shown beta-glucan to activate white blood cells.<sup>1, 2, 3, 4, 5</sup> In fact, there have been hundreds of research papers on beta-glucan since the 1960s.<sup>6</sup> The research indicates that beta-1,3-glucan, in particular, is very effective at activating white blood cells known as macrophages and neutrophils. These cells provide one of the immune system's first lines of defense against foreign invaders. A beta-glucan-activated macrophage or neutrophil can recognize and kill tumor cells, remove cellular debris resulting from oxidative damage, speed up recovery of damaged tissue, and further activate other components of the immune system.<sup>7, 8</sup> Although the research in test tube and animal studies is promising, many questions remain about the effectiveness of beta-glucan as an oral supplement to enhance immune function in humans.

Beta-glucan is the key factor for the cholesterol-lowering effect of oat bran.<sup>9, 10, 11, 12, 13</sup> As with other soluble-fiber components, the binding of cholesterol (and bile acids) by beta-glucan and the resulting elimination of these molecules in the feces is very helpful for reducing blood cholesterol.<sup>14, 15, 16</sup> Results from a number of double-blind trials with either oat- or yeast-derived beta-glucan indicate typical reductions, after at least four weeks of use, of approximately 10% for total cholesterol and 8% for LDL ("bad") cholesterol, with elevations in HDL ("good") cholesterol ranging from zero to 16%.<sup>17, 18, 19, 20, 21</sup>

Like other sources of soluble **fiber** (page 512), beta-glucan is, according to preliminary studies, helpful in reducing the elevation in blood sugar levels that typically follow a meal.<sup>22, 23, 24, 25</sup> Beta-glucan produces this effect by delaying gastric emptying so that dietary sugar is absorbed more gradually, as well as by possibly increasing the tissue sensitivity to insulin. These effects suggest possible benefit in blood sugar control in people with **diabetes** (page 152).

#### Where is it found?

Beta-glucan is found in the cell walls of many yeast and cereal fibers, such as **oats** (page 716), wheat, and barley. As a dietary supplement, beta-glucan is available in liquid form as well as in capsules and tablets.

**Beta-glucan has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>High cholesterol</b> (page 223)
★☆☆	<b>Immune enhancement</b> (page 255)

#### Who is likely to be deficient?

Because beta-glucan is not an essential nutrient, deficiencies do not occur.

#### How much is usually taken?

For lowering **cholesterol** (page 223) levels, the amount of beta-glucan used in clinical trials has ranged from 2,900 to 15,000 mg per day. For enhancing **immune function** (page 255), an effective amount has not yet been determined due to the lack of studies in this application. However, manufacturers of beta-glucan products usually recommend between 50 and 1,000 mg daily (to be taken on an empty stomach), although some products contain as much as 500 mg per capsule.

#### Are there any side effects or interactions?

No side effects have been reported.

## BETA-SITOSTEROL

#### What is it?

Beta-sitosterol is one of a group of organic compounds found in plants that, alone and in combination with similar plant sterols, reduces blood levels of **cholesterol** (page 223).<sup>1, 2, 3</sup>

The reduction of cholesterol levels appears to be because beta-sitosterol blocks absorption of cholesterol.<sup>4</sup> It has also been effective in reducing symptoms of **benign prostatic hyperplasia** (page 58).<sup>5</sup> Although molecules quite similar to beta-sitosterol inhibit **cancer** (page 87) cells in test tubes, the relevance of this information for people remains unknown.<sup>6</sup>

#### Where is it found?

Beta-sitosterol is one of several plant sterols (cholesterol is the main animal sterol) found in almost all plants. High levels are found in rice bran, wheat germ, corn oil, and soybeans. Peanuts and its products, such as peanut oil, peanut butter, and peanut flour, are good sources of plant sterols, particularly beta-sitosterol.<sup>7</sup>

**Beta-sitosterol has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Benign prostatic hyperplasia</b> (page 58)
★☆☆	<b>High cholesterol</b> (page 223)
★☆☆	<b>Athletic performance</b> (page 43) (in combination with beta-sitosterol glucoside for reducing the risk of post-exercise infection)

#### Who is likely to be deficient?

Because beta-sitosterol is not an essential nutrient, deficiencies do not occur.

#### How much is usually taken?

Between 500 mg and 10 grams of beta-sitosterol per day have been used in clinical research to reduce elevated blood **cholesterol** (page 223) levels. Between 60 (20 mg three times per day) and 130 mg per day have been used in trials reporting a reduction in **prostatic hyperplasia** (page 377)-related symptoms.<sup>8, 9</sup>

### Are there any side effects or interactions?

Ingesting plant sterols interferes with **beta-carotene** (page 469) and **vitamin E** (page 609) absorption, resulting in lower blood levels of these nutrients.<sup>10</sup>

## BETAINE (TRIMETHYLGLYCINE)

### What is it?

Betaine (trimethylglycine) functions very closely with **choline** (page 546), **folic acid** (page 520), **vitamin B<sub>12</sub>** (page 598), and a form of the amino acid **methionine** (page 557) known as S-adenosylmethionine (**SAMe** [page 583]).<sup>1, 2</sup> All of these compounds function as “methyl donors.” They carry and donate methyl molecules to facilitate necessary chemical processes. The donation of methyl groups by betaine is very important to proper liver function, cellular replication, and detoxification reactions. Betaine also plays a role in the manufacture of **carnitine** (page 543) and serves to protect the kidneys from damage.<sup>3</sup> Betaine is closely related to choline. The difference is that choline (tetramethylglycine) has four methyl groups attached to it. When choline donates one of these groups to another molecule, it becomes betaine (trimethylglycine). If betaine donates one of its methyl groups, then it becomes dimethylglycine.

Betaine has been reported to play a role in reducing blood levels of **homocysteine** (page 234), a toxic breakdown product of amino-acid metabolism that is believed to promote **atherosclerosis** (page 38) and **osteoporosis** (page 333). While the main nutrients involved in controlling homocysteine levels are folic acid, **vitamin B<sub>6</sub>** (page 600), and **vitamin B<sub>12</sub>** (page 601), betaine has been reported to be helpful in some people whose elevated homocysteine levels did not improve with these other nutrients. Betaine has also been shown to be helpful in certain rare genetic disorders involving **cysteine** (page 502) metabolism.<sup>4, 5, 6, 7, 8</sup> However, in normal situations or with supplementation of the other methyl donors, betaine is not likely to produce any lowering effect on homocysteine levels.<sup>9, 10</sup> Its primary use as a nutritional supplement is in supporting proper liver function.

Betaine is often referred to as a “lipotropic factor” because of its ability to help the liver process fats (lipids). In animal studies, betaine supplementation has been shown to protect against chemical damage to the liver.<sup>11, 12, 13, 14</sup> The first stage of liver damage that results

from drinking **alcohol** (page 12) is the accumulation of fat in the liver (alcohol-induced fatty liver disease). Betaine, because of its lipotropic effects, has been shown to produce significant improvements in this condition in several human clinical studies.<sup>15, 16</sup> Betaine has been studied in clinical trials conducted in Germany, Italy, and France in the treatment of **alcohol-related liver disease** (page 290).<sup>17, 18, 19, 20, 21, 22, 23, 24</sup> Some success was noted in these studies, but the popularity of betaine for alcohol-related liver disease has been supplanted by **SAMe** (page 583) and **milk thistle** (page 710) extract. However, it has recently been suggested that betaine may be a more cost-effective method as a first-step therapy for alcohol-induced fatty liver disease.<sup>25</sup>

Betaine is also showing promise as a toothpaste ingredient, as it has been shown to produce significant relief of dry mouth.<sup>26</sup>

### Where is it found?

Dietary sources of betaine include fish, beets, and legumes. Betaine is most widely available as **betaine hydrochloride** (page 473) (betaine-HCl), but that form is used primarily as a source of hydrochloric acid for people with **hypochlorhydria** (page 260) (low stomach acid). The forms used specifically to provide betaine are betaine citrate and betaine aspartate. These forms have also been used to improve liver function.

**Betaine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Alcohol-induced fatty liver <b>Hepatitis</b> (page 220) (nonalcoholic steatohepatitis) <b>Homocysteine (high)</b> (page 234)
★☆☆	<b>Atherosclerosis</b> (page 38)

### Who is likely to be deficient?

Betaine is not an essential nutrient, and thus no deficiency state exists.

### How much is usually taken?

For people with alcohol-induced fatty liver, the recommended amount for betaine citrate or betaine aspartate supplementation is 1,000 to 2,000 mg three times daily. Lower amounts are often used as nutritional support for general liver health, although use of betaine in this manner has not undergone clinical research.

### Are there any side effects or interactions?

No side effects with betaine at recommended levels have been noted.

## BETAINE HYDROCHLORIDE

### What is it?

Betaine hydrochloride is an acidic form of betaine, a vitamin-like substance found in grains and other foods. Betaine hydrochloride is recommended by some doctors as a supplemental source of hydrochloric acid for people who have a deficiency of stomach acid production (hypochlorhydria).

A deficiency of gastric acid secretion increases the likelihood and severity of certain bacterial and parasitic intestinal infections. A normal stomach's level of gastric acid is sufficient to destroy bacteria.<sup>1</sup> In one study, most fasting people who had normal acidity in the stomach had virtually no bacteria in the small intestine. Some bacterial colonization of the stomach occurred in people who had low levels of hydrochloric acid.<sup>2</sup>

### Where is it found?

Gastric acid is produced by the parietal cells of the stomach. The acidity is quite strong in a normal stomach. In fact, the stomach can be between 100,000 and almost 1,000,000 times more acidic than water.

**Betaine hydrochloride (HCl) has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Acne Rosacea</b> (page 4) <b>Asthma</b> (page 32) <b>Chronic candidiasis</b> (page 109) <b>Dermatitis herpetiformis</b> (page 151) <b>Food allergies</b> (page 14) <b>Gallstones</b> (page 193) <b>Gastroesophageal reflux disease</b> (page 198) (GERD) <b>Hives</b> (page 245) <b>Indigestion</b> (page 260) <b>Iron-deficiency anemia</b> (page 278) (as an adjunct to supplemental iron) <b>Rheumatoid arthritis</b> (page 387) Tic douloureux <b>Vitiligo</b> (page 445)

### Who is likely to be deficient?

Some research suggests that people with a wide variety of chronic disorders, such as **allergies** (page 14),<sup>3</sup> **asthma** (page 32),<sup>4</sup> and **gallstones** (page 193),<sup>5</sup> do not produce adequate amounts of stomach acid.

### How much is usually taken?

Betaine HCl is the most common hydrochloric acid-containing supplement. Normally it comes in tablets or capsules measured in grains or milligrams. Only people who have reduced levels of stomach acid ("hypochlorhydria") should take betaine HCl; this condition can be diagnosed by a doctor. When appropriate, some doctors recommend taking one or more tablets or capsules, each 5–10 grains (325–650 mg), with a meal that contains protein. Occasionally, **betaine (trimethylglycine)** (page 472) is recommended to reduce blood levels of a substance called **homocysteine** (page 234), which is associated with **heart disease** (page 98). This form of betaine is different from betaine HCl.

### Are there any side effects or interactions?

Large amounts of betaine HCl can burn the lining of the stomach. If a burning sensation is experienced, betaine HCl should be immediately discontinued. People should not take more than 10 grains (650 mg) of betaine HCl without the recommendation of a physician. All people with a history of **peptic ulcers** (page 349), **gastritis** (page 195), or gastrointestinal symptoms—particularly **heartburn** (page 260)—should see a doctor before taking betaine HCl. People taking nonsteroidal anti-inflammatory drugs (NSAIDs), cortisone-like drugs, or other medications that might cause a peptic ulcer should not take betaine HCl. Betaine HCl helps make some minerals and other nutrients more absorbable.<sup>6,7</sup>

Biotin

## BIOTIN

### What is it?

Biotin, a water-soluble B vitamin, acts as a coenzyme in the metabolism of protein, fats, and carbohydrates.

### Where is it found?

Good dietary sources of biotin include organ meats, oatmeal, egg yolk, **soy** (page 587), mushrooms, bananas, peanuts, and **brewer's yeast** (page 480). Bacteria in the intestine also produce significant amounts of biotin, but evidence is conflicting as to whether biotin

produced by intestinal bacteria is present at a location or is in a form that permits significant absorption by the body.<sup>1</sup>

**Biotin has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Brittle nails</b> (page 79) <b>Diabetes</b> (page 152) <b>Pregnancy</b> (page 363)
★★★	<b>Seborrheic dermatitis</b> (page 400) (cradle cap)

**Who is likely to be deficient?**

Certain rare inborn diseases can leave people with depletion of biotin due to the inability to metabolize the vitamin normally. A dietary deficiency of biotin, however, is quite uncommon, even in those consuming a diet low in this B vitamin. Nonetheless, if someone eats large quantities of raw egg whites, a biotin deficiency can develop, because a protein in the raw egg white inhibits the absorption of biotin. Cooked eggs do not present this problem. Long-term antibiotic use can interfere with biotin production in the intestine and increase the risk of deficiency symptoms, such as **dermatitis** (page 151), **depression** (page 145), hair loss,<sup>2</sup> **anemia** (page 25), and nausea. Long-term use of anti-seizure medications may also lead to biotin deficiency.<sup>3</sup> **Alcoholics** (page 12), people with **inflammatory bowel disease** (page 269), and those with diseases of the stomach have been reported to show evidence of poor biotin status. However, the usefulness of biotin supplementation for these people remains unclear.<sup>4</sup> In animals, and possibly in humans, biotin deficiency can cause **birth defects** (page 63).<sup>5</sup> As biotin deficiency may occur in as many as 50% of pregnant women,<sup>6</sup> it seems reasonable to use a prenatal multiple vitamin and mineral formula that contains biotin.

**How much is usually taken?**

The ideal intake of biotin is unknown. However, the amount of biotin found in most diets, combined with intestinal production, appears to be adequate for preventing deficiency symptoms. Researchers have estimated that 30 mcg per day appears to be an adequate intake for adults.<sup>7</sup> Typically, consumption from a Western diet has been estimated to be 30–70 mcg per day. Larger amounts of biotin (8–16 mg per day) may be

supportive for people with **diabetes** (page 152) by lowering blood glucose levels and by preventing diabetic neuropathy.<sup>8,9</sup> Biotin in the amount of 2.5 mg per day strengthened the fingernails of two-thirds of a group of people with **brittle nails** (page 79), according to one clinical trial.<sup>10</sup>

**Are there any side effects or interactions?**

Excess intake of biotin is excreted in the urine; no toxicity symptoms have been reported.

Biotin works with some other B vitamins, such as **folic acid** (page 520), **pantothenic acid** (page 568) (vitamin B<sub>5</sub>), and **vitamin B<sub>12</sub>** (page 601). However, no solid evidence indicates that people supplementing with biotin also need to take these other vitamins. Symptoms of pantothenic acid or **zinc** (page 614) deficiency have been reported to be lessened with biotin,<sup>11</sup> though people with these deficiencies should supplement with the nutrients in which they are deficient. Researchers have speculated that biotin and **alpha lipoic acid** (page 464) may compete with each other for absorption or uptake into cells; but little is known about the importance of these interactions in humans.<sup>12</sup>

There is one report of a 76-year-old woman who developed a life-threatening condition (eosinophilic pleuropericardial effusion) while taking 10 mg of biotin per day and 300 mg of pantothenic acid per day.<sup>13</sup> However, it is not clear whether the vitamins caused the problem.

## BLUE-GREEN ALGAE

**What is it?**

Blue-green algae, of which spirulina is a well-known example, is a group of 1,500 species of microscopic aquatic plants. The two most common species used for human consumption are *Spirulina maxima* and *Spirulina platensis*. Spirulina is particularly rich in protein and also contains **carotenoids** (page 488), vitamins, minerals, and essential fatty acids.<sup>1</sup>

Spirulina's **vitamin B<sub>12</sub>** (page 601) content does not appear to be readily usable by people.<sup>2</sup> Most health benefits to humans claimed for spirulina and other blue-green algae supplementation are supported by anecdotes rather than scientific research. Test tube and animal studies have demonstrated several properties of large amounts of spirulina or spirulina extracts, including **antioxidant** (page 467),<sup>3</sup> antiviral,<sup>4,5</sup> **anticancer**

(page 87),<sup>6, 7, 8, 9</sup> **anti-allergy** (page 14),<sup>10, 11</sup> **immune-enhancing** (page 255),<sup>12, 13, 14</sup> liver-protecting,<sup>15, 16, 17</sup> blood vessel-relaxing,<sup>18</sup> and blood lipid-lowering<sup>19, 20</sup> effects.

A small, controlled study found that **overweight** (page 446) people taking 8.4 grams per day of spirulina lost an average of three pounds in four weeks compared with one and a half pounds when taking placebo, though this difference was not statistically significant and no effects on **blood pressure** (page 246) or serum cholesterol were observed.<sup>21</sup> A later, controlled trial found a small **cholesterol-lowering** (page 223) effect when 4.2 grams of spirulina per day were taken for eight weeks, but serum triglycerides, blood pressure, and body weight were unchanged.<sup>22</sup>

#### Where is it found?

Blue-green algae grow in some lakes, particularly those rich in salts, in Central and South America, and Africa. They are also grown in outdoor tanks specifically to be harvested for nutritional supplements.

**Blue-green algae have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Weight loss and obesity</b> (page 446)

#### Who is likely to be deficient?

As it is not an essential nutrient, blue-green algae is not associated with a deficiency state. However, people who do not consume several servings of vegetables per day could benefit from the **carotenoids** (page 488) and other nutrients in blue-green algae. Since it is a complete protein, it can be used in place of some of the protein in a healthy diet. However, very large amounts are required to provide significant quantities of these nutrients from blue-green algae.

#### How much is usually taken?

Blue-green algae can be taken as a powder or as flakes, capsules, or tablets. The typical manufacturer's recommended intake is 2,000–3,000 mg per day divided throughout the day. However, typical amounts shown to have helpful properties in animal studies would be equivalent to 34 grams per day or more, for a 150-pound human.

#### Are there any side effects or interactions?

Few side effects have been reported from the ingestion of blue-green algae. However, as blue-green algae can accumulate heavy metals from contaminated water, consuming blue-green algae could increase the body's load of lead, mercury, and cadmium,<sup>23</sup> though noncontaminated blue-green algae have been identified.<sup>24</sup> Another popular species of blue-green algae, *Aphanizomenon flos-aquae*, has been found to produce toxins.<sup>25</sup> A few reports also describe allergic reactions to blue-green algae. Animal studies have found spirulina to be safe during **pregnancy** (page 363).<sup>26, 27, 28</sup>

There is one case report of a man who developed liver damage while taking spirulina.<sup>29</sup> As he was also taking three prescription medications, it is not clear whether the spirulina caused or contributed to the liver injury.

## BORAGE OIL

#### What is it?

Borage oil is derived from the seeds of the borage (*Borago officinalis*) plant, a large plant with blue, star-shaped flowers found throughout Europe and North Africa and naturalized to North America.<sup>1</sup>

Borage oil, **evening primrose oil** (page 511), and black currant seed oil contain gamma linolenic acid (GLA), a fatty acid that the body converts to a hormone-like substance called prostaglandin E<sub>1</sub> (PGE<sub>1</sub>). PGE<sub>1</sub> has anti-inflammatory properties and may also act as a blood thinner and blood vessel dilator. Linoleic acid, a common fatty acid found in nuts and seeds and most vegetable oils (including borage oil), should theoretically convert to PGE<sub>1</sub>. Many things can interfere with this conversion, however, including disease; the aging process; saturated fat; hydrogenated oils; blood sugar problems; and inadequate **vitamin C** (page 604), **magnesium** (page 551), **zinc** (page 614), and **B vitamins** (page 603). Supplements that provide GLA circumvent these conversion problems, leading to more predictable formation of PGE<sub>1</sub>.<sup>2</sup>

Borage seed oil is the richest source of GLA, containing 20 to 26%. While GLA from evening primrose oil has been widely researched, scientific evidence supporting the use of borage oil has been limited. Nonetheless, one preliminary trial<sup>3</sup> and two double-blind trials<sup>4, 5</sup> have shown that borage oil, 1.1–2.8 grams per day for at least three months, reduces symptoms of rheumatoid arthritis.

Borage oil has also been used to treat people with atopic dermatitis (**eczema** [page 177]) in preliminary trials, with reductions in skin inflammation, dryness, scaliness, and itch, without side effects being reported.<sup>6</sup> However, a controlled study using 360 mg daily of GLA from borage oil in patients with atopic dermatitis (3 to 17 years of age) was unable to reproduce these results.<sup>7</sup> In another preliminary study, a group of children with infantile seborrheic dermatitis were treated with borage oil (0.5 ml) applied to the diaper region twice daily.<sup>8</sup> Within 10 to 12 days, all of the children were free from skin lesions, even in the areas not treated with borage. Moreover, using the oil topically two to three times a week kept the seborrhea in remission until the patients were six to seven months old. There were no relapses after the oil was discontinued.

#### Where is it found?

Borage oil is found primarily in supplements. Its presumed active ingredient, GLA, can also be found in black currant seed oil and **evening primrose oil** (page 511) supplements. However, it is not known whether the effects of these three oils in the body, are the same.

**Borage oil has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Rheumatoid arthritis (page 387)
★★☆	Eczema (page 177)
★☆☆	Infantile seborrheic dermatitis (page 400) (topical)

#### Who is likely to be deficient?

Many people in Western societies may be at least partially GLA-deficient as a result of aging, glucose intolerance, dietary fat intake, and other problems, though the exact incidence of deficiency remains unknown. People with deficiencies benefit from supplemental GLA intake from borage oil, black currant seed oil, or **evening primrose oil** (page 511).

Those with **premenstrual syndrome** (page 368),<sup>9</sup> **diabetes** (page 152),<sup>10</sup> scleroderma,<sup>11</sup> Sjogren's syndrome,<sup>12</sup> **tardive dyskinesia** (page 425),<sup>13</sup> **eczema** (page 177),<sup>14</sup> and other skin conditions<sup>15</sup> may have a metabolic block that interferes with the body's ability to make GLA. However, most clinical trials supplement-

ing GLA for these conditions has used evening primrose oil, and not borage oil.

#### How much is usually taken?

For the treatment of **rheumatoid arthritis** (page 387), the amounts of GLA from borage used in successful double-blind trials were 1.4–2.8 grams daily for at least two months.<sup>16, 17</sup> Although 360 mg of GLA daily from borage oil has been used to treat people with **eczema** (page 177), controlled research has not supported its use for this condition.<sup>18</sup> Topically, 0.5 ml of borage oil may be applied to areas of **seborrhea** (page 400) daily for two weeks, and then three times a week until the condition is stable.<sup>19</sup>

#### Are there any side effects or interactions?

Borage seeds contain small amounts of liver toxins called pyrrolizidine alkaloids (PA). However, testing has not demonstrated the presence of the alkaloid in the seed oil.<sup>20</sup> Most commercially available borage seed oil is, therefore, likely to be PA-free and presents no risk of PA toxicity. Minor side effects from borage oil use can include bloating, nausea, **indigestion** (page 260), and headache.<sup>21</sup>

## BORIC ACID

#### What is it?

Boric acid is a chemical substance with mild antiseptic, antifungal, and antiviral properties.

Boric acid is commonly used in the form of suppositories inserted in the vagina to treat **yeast infection** (page 454). In one study of 100 women with chronic yeast **vaginitis** (page 438) that had failed to respond to treatment with over-the-counter or prescription antifungal medicines, 98% of the women successfully treated their **infections** (page 265) with boric acid capsules inserted into the vagina twice per day for two to four weeks.<sup>1</sup> Several commercial douching products contain boric acid.

The antiseptic activity of boric acid is also used in commercial "artificial tears" and eyewash products.

Boric acid also has antiviral activity. Topical application of diluted boric acid, in the form of sodium borate ointment, has been found to shorten the duration of **cold sores** (page 119) in a double-blind trial.<sup>2</sup> The duration of cold sores was approximately four days in the

group receiving boric acid, compared with six days in the placebo group.

### Where is it found?

Boric acid is a white, odorless powder or crystalline substance that is available in many over-the-counter pharmaceutical products for topical use, alone as a topical antiseptic, and in suppository form.

**Boric acid has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Yeast infection</b> (page 454)
★★★	<b>Cold sores</b> (page 119)

### Who is likely to be deficient?

Boric acid is not taken internally and is not a nutrient; no deficiency exists.

### How much is usually taken?

Boric acid is available in powder form from a pharmacy, without a prescription. This powder can be packed into an empty gelatin capsule and used as a suppository. For women with **vaginitis** (page 438), some doctors recommend that one such capsule, containing 600 mg of boric acid, be inserted into the vagina each night for two weeks. Some health food stores have suppositories that contain a combination of boric acid and herbs.

In the trial studying **cold sores** (page 119), an ointment diluted to 4% boric acid was applied four times per day. Because of the potential toxicity of such a preparation, people should consult their doctors before using boric acid.

### Are there any side effects or interactions?

Boric acid suppositories should not be used during **pregnancy** (page 363). Boric acid is very toxic when taken internally and should also never be used on open **wounds** (page 319). When boric acid enters the body, it can cause nausea, vomiting, **diarrhea** (page 163), dermatitis, kidney damage, acute failure of the circulatory system, and even death. In the past, boric acid was used as a topical treatment for infants with diaper rash. However, even in diluted (3%) form it caused significant toxicity and two deaths.<sup>3</sup> Therefore, boric acid should not be applied to the skin of infants and small children. In fact, experts in the field have stated, "The

minor therapeutic value of this compound, in comparison with its potential as a poison, has led to the general recommendation that it no longer be used as a therapeutic agent."<sup>4</sup> However, in more recent research, no serious side effects were reported when boric acid was used as a treatment for **vaginitis** (page 438).

## BORON

### What is it?

Boron is a nonmetallic element present in the diet and in the human body in trace amounts. Whether boron is an essential nutrient for humans remains in debate.

Boron appears to affect the metabolism of **calcium** (page 483), **magnesium** (page 551), **copper** (page 499), phosphorus, and **vitamin D** (page 607). Preliminary research suggests that boron might affect bone and joint health, but little specific information is known. The most promising research with boron has linked supplementation to reduced loss of calcium in urine. This effect might lead to a lower risk of **osteoporosis** (page 333), but decreased loss of calcium from boron supplementation occurs mostly when people are not getting enough magnesium in their diets.<sup>1</sup>

### Where is it found?

Raisins, prunes, and nuts are generally excellent sources of boron. Fruit (other than citrus), vegetables, and legumes also typically contain significant amounts. Actual amounts vary widely, depending upon boron levels in soil where the food is grown.

**Boron has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Osteoarthritis</b> (page 328)
	<b>Osteoporosis</b> (page 333)
	<b>Rheumatoid arthritis</b> (page 387)

### Who is likely to be deficient?

As boron is not yet considered an essential nutrient for humans, it is not clear whether deficiencies occur. However, diets that are low in fruit, vegetables, legumes, and nuts provide less boron than diets that contain more of these foods.

### How much is usually taken?

A leading boron expert has suggested 1 mg per day of boron is a reasonable amount to consume.<sup>2</sup> People who eat adequate amounts of produce, nuts, and legumes are likely already eating two to six times this amount.<sup>3</sup> Therefore, whether the average person would benefit by supplementing with this mineral remains unclear.

### Are there any side effects or interactions?

Accidental acute exposure to high levels of boron can cause nausea, vomiting, abdominal pain, rash, convulsions, and other symptoms.<sup>4</sup> Although chronic exposures can cause related problems, the small (usually 1–3 mg per day) amounts found in supplements have not been linked with toxicity in most reports. Nonetheless, in one double-blind trial using 2.5 mg of boron per day for two months, hot flashes and night sweats worsened in 21 of 43 women, though the same symptoms improved in 10 others.<sup>5</sup> Women whose have hot flashes or night sweats have been diagnosed as **menopausal** (page 311) symptoms and who supplement with boron should consider discontinuing use of boron-containing supplements to see if the severity of their symptoms is reduced.

One study found that 3 mg per day resulted in increased estrogen and testosterone levels.<sup>6</sup> Increased estrogen has also been reported in several women taking 2.5 mg per day.<sup>7</sup> The increase in estrogen is of concern because it could theoretically increase the risk of several **cancers** (page 87). Although no increased risk of cancer has been reported in areas of the world where boron intake is high, some doctors recommend that supplemental boron intake be limited to a maximum of 1 mg per day.

The relationship between boron and other minerals is complex and remains poorly understood. Boron may conserve the body's use of **calcium** (page 483), **magnesium** (page 551), and **vitamin D** (page 607). In one study, the ability of boron to reduce urinary loss of calcium disappeared when subjects were also given magnesium.<sup>8</sup> Therefore, boron may provide no special benefit in maintaining bone mass in the presence of adequate amounts of dietary magnesium.

## BOVINE COLOSTRUM

### What is it?

Bovine colostrum is the pre-milk liquid produced from the mammary glands of cows during the first 24 to 48 hours after giving birth.

Bovine colostrum is rich in immunoglobulins (antibodies), growth factors, various proteins, and enzymes. The question is whether these factors, which are meant for the calf, exert any effects in humans. Bovine colostrum may turn out to be an important nutritional supplement, but for now there are no conclusive data to support manufacturers' claims. Although various components of bovine colostrum theoretically may produce some benefits, there are no studies where bovine colostrum—in the forms that are commercially available—has been given to humans and shown benefits.

It has been claimed that bovine colostrum can help fight certain **infections** (page 265). However, the research studies used to support that claim used colostrum derived from cows immunized in a way that caused them to produce unusually large amounts of a specific antibody in their colostrum. For example, in a double-blind study, children with **diarrhea** (page 163) caused by a rotavirus were treated with immunoglobulins extracted from colostrum derived from cows immunized with rotavirus. Compared with the placebo, administration of the immunoglobulins significantly reduced the amount of diarrhea and the amount of oral rehydration solution required. In addition, the rotavirus was eliminated from the stool significantly more rapidly in the immunoglobulin group than in the placebo group (1.5 days vs. 2.9 days).<sup>1</sup>

In addition to a positive effect against acute rotavirus diarrhea,<sup>2,3</sup> there is also evidence that specific forms of colostrum (derived from specially immunized cows or those with confirmed presence of specific antibodies) are effective against diarrhea caused by *Cryptosporidium parvum*, *Helicobacter pylori*, *Escherichia coli*, and *Clostridium difficile*.<sup>4,5,6,7,8</sup> However, it is not known whether commercially available colostrum provides significant amounts of the specific immunoglobulins that are active against these organisms. Furthermore, unless the immunoglobulins are present in high enough concentrations, the preparation is not likely to be effective. There is evidence that the majority of the antimicrobial effect of both bovine colostrum and one of its chief antibiotic components (lactoferrin) are destroyed by gastric secretions and by the digestive enzyme, trypsin.<sup>9</sup>

Bovine colostrum contains bovine versions of many human growth factors, including insulin-like growth factor, transforming growth factor, epithelial growth factor, and even growth hormone, that are capable of stimulating muscle growth. The concentration of bovine insulin-like growth factor I (ILGF-I) in colostrum ranges from 200 to 2,000 mcg/L, compared

with less than 10 mcg/L in normal cow's milk.<sup>10</sup> Thus, in theory, bovine colostrum might be able to stimulate muscle growth in humans. However, although bovine ILGF-I has been shown to be identical to human ILGF-I in some analytical studies<sup>11</sup> and to be absorbed and transported into the circulation in calves,<sup>12</sup> the effects of bovine ILGF-I and other bovine growth substances in humans after oral administration, has not been determined in clinical trials.

In a preliminary study of male athletes, supplementation with 125 ml of colostrum per day for eight days produced a statistically significant increase in the serum concentration of insulin-like growth factor.<sup>13</sup> However, the magnitude of the increase was small, and the clinical significance of that change is not clear. Thus, claims that bovine colostrum can help burn fat and promote muscle growth by raising the level of ILGF-I or other molecules must be considered premature.

Bovine colostrum may be helpful in protecting against **peptic ulcer** (page 349) formation caused by nonsteroidal anti-inflammatory drugs (NSAIDs) such as aspirin, ibuprofen, and indomethacin. In a study in rats, pretreatment with 0.5 or 1.0 ml of a colostrum preparation reduced indomethacin-induced gastric injury by 30% and 60%, respectively.<sup>14</sup> Whether bovine colostrum exerts this effect in humans has not been determined.

Claims that bovine colostrum elevates mood, that "colostrum is a natural and healthy means of stimulating the brain to release serotonin and dopamine and prolong their re-uptake," or that "colostrum also activates the release of other chemicals in the brain that affect alertness and concentration" are unsubstantiated.

#### Where is it found?

Bovine colostrum is available in capsules, tablets, powdered drink mixes, liquid preparations, food bars, and skin care products.

#### Bovine colostrum has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Certain types of infectious <b>diarrhea</b> (page 163)

#### Who is likely to be deficient?

As bovine colostrum is not an essential nutrient, no deficiency state exists.

#### How much is usually taken?

Most manufacturers recommend 1,000 to 4,000 mg per day of freeze-dried colostrum.

#### Are there any side effects or interactions?

None are known.

## BRANCHED-CHAIN AMINO ACIDS

#### What are they?

The branched-chain **amino acids** (page 465) (BCAAs) are leucine, isoleucine, and valine. BCAAs are considered essential amino acids because human beings cannot survive unless these amino acids are present in the diet.

BCAAs are needed for the maintenance of muscle tissue and appear to preserve muscle stores of glycogen (a storage form of carbohydrate that can be converted into energy).<sup>1</sup> BCAAs also help prevent muscle protein breakdown during exercise.<sup>2</sup>

Some research has shown that BCAA supplementation (typically 10–20 grams per day) does not result in meaningful changes in body composition,<sup>3</sup> nor does it improve exercise performance<sup>4, 5, 6, 7, 8</sup> or enhance the effects of physical training.<sup>9, 10</sup> However, BCAA supplementation may be useful in special situations, such as preventing muscle loss at high altitudes<sup>11</sup> and prolonging endurance performance in the heat.<sup>12</sup> Studies by one group of researchers suggest that BCAA supplementation may also improve exercise-induced declines in some aspects of mental functioning.<sup>13, 14, 15</sup>

BCAAs can activate glutamate dehydrogenase—an **enzyme** (page 506) that is deficient in amyotrophic lateral sclerosis (ALS), also called Lou Gehrig's disease. In one double-blind trial, 26 grams per day of BCAA supplements helped those with ALS maintain muscle strength.<sup>16</sup> However, a larger study was ended early when people using BCAAs not only failed to improve, but experienced higher death rates than the placebo group.<sup>17</sup> Other studies have shown no benefit of BCAA supplementation for ALS or other neuromuscular diseases,<sup>18, 19</sup> though a small group of people suffering from diseases of the nervous system collectively called spinocerebellar degeneration did improve when given BCAAs in a preliminary study.<sup>20</sup>

One study investigating the advantages of BCAA

supplementation for people with **diabetes** (page 152) undergoing an intense exercise program found no additional benefit of BCAAs on reducing abdominal fat or improving glucose metabolism.<sup>21</sup>

Patients with liver diseases that lead to coma—called hepatic encephalopathy—have low concentrations of BCAAs and excess levels of certain other amino acids. Preliminary research suggested that people with this condition might be helped by BCAAs. Double-blind studies have produced somewhat inconsistent results,<sup>22, 23, 24</sup> but a reanalysis of these studies found an overall benefit for the symptoms of encephalopathy.<sup>25</sup> Therapeutic effects of BCAAs have also been shown in children with liver failure<sup>26</sup> and adults with **cirrhosis of the liver** (page 290).<sup>27</sup> Any treatment of people with liver failure requires the direction of a physician.

People with chronic kidney failure may also benefit from BCAA supplementation. A preliminary study found improved breathing and sleep quality in people given intravenous BCAAs during kidney dialysis.<sup>28</sup>

**Phenylketonuria** (page 354) (PKU) is a genetic disease that causes abnormally high amounts of **phenylalanine** (page 568) and its end products to accumulate in the blood, causing damage to the nervous system. A controlled trial demonstrated that regular use of BCAAs by adolescents and young adults with PKU, improved performance on some tests of mental functioning.<sup>29</sup> This outcome makes sense because BCAAs may compete with phenylalanine, reducing its toxic effects.

In **tardive dyskinesia** (page 425), phenylalanine levels have also been reported to be elevated. As a result, one group of researchers gave tardive dyskinesia patients BCAAs (from 150 mg per 2.2 pounds body weight up to 209 mg per 2.2 pounds body weight) after breakfast and one hour before lunch and dinner for two weeks.<sup>30</sup> The BCAA mixture included equal parts valine and isoleucine plus 33% more leucine than either of the other two amino acids. Of nine patients so treated, six had at least a 58% decrease in symptoms, and all people in the study had a decrease of at least 38% in symptoms.

### Where are they found?

Dairy products and red meat contain the greatest amounts of BCAAs, although they are present in all protein-containing foods. **Whey** (page 613) protein and egg protein supplements are other sources of BCAAs. BCAA supplements provide the **amino acids** (page 465) leucine, isoleucine, and valine.

**BCAAs have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Kidney failure (intravenous BCAAs) <b>Liver cirrhosis</b> (page 290) <b>Phenylketonuria</b> (page 354)
★☆☆	<b>Athletic performance</b> (page 43) (for high altitude and extreme temperature only) Hepatic encephalopathy Spinocerebellar degeneration <b>Tardive dyskinesia</b> (page 425)

### Who is likely to be deficient?

Only a person deficient in protein would become deficient in BCAAs, because most foods that are sources of protein supply BCAAs. Few people in Western societies are protein deficient.

### How much is usually taken?

Most diets provide an adequate amount of BCAAs for most people, which is about 25–65 mg per 2.2 pounds of body weight.<sup>31, 32</sup> Athletes involved in intense training often take 5 grams of leucine, 4 grams of valine, and 2 grams of isoleucine per day to prevent muscle loss and increase muscle gain, though most research does not support this use of BCAAs.

### Are there any side effects or interactions?

Side effects have not been reported with the use of BCAAs. Until more research is conducted, people with ALS should avoid taking supplemental BCAAs. In one study, supplementation with a large amount of BCAAs (60 grams) caused alterations in the blood levels of tryptophan, phenylalanine, and tyrosine.<sup>33</sup> The changes in the blood levels of these amino acids could, in theory, cause depression in susceptible individuals. Until more is known, individuals with a history of depression should consult a doctor before supplementing with BCAAs. People with **kidney** (page 284) or **liver** (page 290) disease should not consume high amounts of amino acids without consulting their doctor.

## BREWER'S YEAST

### What is it?

Brewer's yeast is the dried, pulverized cells of *Saccharomyces cerevisiae*, a type of fungus, and is a rich source

of **B-complex vitamins** (page 603), protein (providing all essential **amino acids** [page 465]), and minerals, including a biologically active form of **chromium** (page 493) known as glucose tolerance factor (GTF). Brewer's yeast is usually a by-product of the brewing industry and should not be confused with nutritional yeast or torula yeast, which are low in chromium.

### Where is it found?

Brewer's yeast, which has a very bitter taste, is recovered after being used in the beer-brewing process. Brewer's yeast can also be grown specifically for harvest as a nutritional supplement. "De-bittered" yeast is also available, though most yeast sold in health food stores that does not taste bitter is not real brewer's yeast.

**Brewer's yeast has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Diabetes</b> (page 152) <b>High cholesterol</b> (page 223)
★★☆	<b>Diarrhea</b> (page 163) (infectious)

### Who is likely to be deficient?

Brewer's yeast is not an essential nutrient, but it can be used as a source of **B-complex** (page 603) vitamins and protein. It is by far the best source of **chromium** (page 493), both in terms of quantity and bio-availability.

### How much is usually taken?

Brewer's yeast is often taken as a powder, or as tablets or capsules. High-quality brewer's yeast powder or flakes contain as much as 60 mcg of **chromium** (page 493) per tablespoon (15 grams). When doctors recommend brewer's yeast, they will often suggest 1–2 tablespoons (15–30 grams) of this high-potency bulk product per day. Remember, if it is not bitter, it is not likely to be real brewer's yeast and therefore will not contain biologically active chromium. In addition, "primary grown" yeast (i.e., that grown specifically for harvest, as opposed to that recovered in the brewing process) may not contain GTF.

### Are there any side effects or interactions?

Side effects have not been reported from the use of brewer's yeast, although **allergies** (page 14) to it exist in some people. It is not related to *Candida albicans* fungus, which causes **yeast infection** (page 454).

Because it contains a highly biologically active form of **chromium** (page 493), supplementation with brewer's yeast could potentially enhance the effects of drugs for **diabetes** (page 163) (e.g., insulin or other blood sugar-lowering agents) and possibly lead to **hypoglycemia** (page 251). Therefore, people with diabetes taking these medications should supplement with chromium or brewer's yeast only under the supervision of a doctor.

*Saccharomyces boulardii* (page 575) is registered in Europe under the name *Saccharomyces cerevisiae*, though the manufacturer states that *S. boulardii* is not the same as brewer's yeast (*S. cerevisiae*). There is a case report of a person with severely impaired **immune function** (page 255) who, after receiving treatment with *S. boulardii*, developed an invasive fungal **infection** (page 265) identified as *S. cerevisiae*.<sup>1</sup> People with severe impairment of the immune system should therefore not take brewer's yeast or *S. boulardii* unless supervised by a doctor.

## BROMELAIN

### What is it?

Bromelain, derived from the pineapple plant, is one of a group of proteolytic **enzymes** (page 506) (enzymes capable of digesting protein).

It is widely believed that most orally ingested enzymes are destroyed by the digestive juices prior to being absorbed. However, there is evidence that significant amounts of bromelain can be absorbed intact.<sup>1</sup> Proteolytic enzymes *other than* bromelain are often used with people who suffer from **malabsorption** (page 304). Although bromelain in combination with other enzymes and ox bile has been reported to help digest food,<sup>2</sup> it is generally not used for this purpose. However, bromelain does contribute to the digestion of protein, and may therefore be used as a digestive aid. Although many doctors assume that other proteolytic enzymes, such as those found in pancreatin, are more effective than bromelain in helping digestion and absorption, almost no research compares the relative effects of these enzymes.

Bromelain is an anti-inflammatory agent and for this reason is helpful in healing **minor injuries** (page 319), particularly **sprains and strains** (page 412), muscle injuries, and the **pain** (page 338), swelling, and tenderness that accompany sports injuries.<sup>3, 4, 5</sup> Topically

applied bromelain in the form of a cream may be beneficial for frostbite,<sup>6</sup> possibly enhancing the rate of healing,<sup>7</sup> and for cleaning debris from **burns** (page 85).<sup>8</sup> These uses of bromelain should be supervised by a doctor.

Also as a result of its anti-inflammatory effect, bromelain has been found to dramatically reduce post-operative swelling in controlled human research.<sup>9</sup> Double-blind research has found bromelain effective in reducing swelling, bruising,<sup>10</sup> and pain, for women having minor surgery in conjunction with giving birth (episiotomy).<sup>11</sup>

The anti-inflammatory effect of bromelain is the probable reason this enzyme has been found effective for people suffering from **sinusitis** (page 407).<sup>12</sup> Some of the evidence supporting bromelain in the treatment of sinusitis comes from double-blind research.<sup>13</sup>

Bromelain, in combination with trypsin (another enzyme), may enhance the effect of antibiotics in people with a urinary tract infection (**UTI** [page 436]). In a double-blind study, 100% of people who received bromelain/trypsin in combination with antibiotics had a resolution of their UTIs, compared to only 46% of those who received antibiotics alone.<sup>14</sup>

Again, probably due to its anti-inflammatory action, bromelain was reported to help patients with **rheumatoid arthritis** (page 387) in preliminary research.<sup>15</sup> In that trial, in which bromelain was given for varying (3-week to 13-month) periods, 73% had good to excellent results.

Bromelain is a natural blood thinner because it prevents excessive blood platelet stickiness.<sup>16</sup> This may explain, in part, the positive reports in a few clinical trials of bromelain to decrease symptoms of **angina** (page 27) and thrombophlebitis.<sup>17, 18</sup> In addition, bromelain reduces the thickness of mucus, which may benefit patients with **asthma** (page 32) or chronic **bronchitis** (page 80).<sup>19</sup>

Preliminary evidence in both animals and people suggests that bromelain may possess antitumor activity, though the true importance of this effect is poorly understood.<sup>20</sup>

Bromelain can induce beneficial changes in white blood cells with possible effects on **immune function** (page 255).<sup>21, 22</sup> However, whether these effects would help people with immune system problems remains unclear.

### Where is it found?

Bromelain is found mostly in the stems of pineapples and is available as a dietary supplement.

**Bromelain has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Sinusitis</b> (page 407) <b>Wound healing</b> (page 319)
★★☆	<b>Post-surgical healing</b> (page 357) <b>Prostatitis</b> (page 377) (NBP, PD) <b>Sprains and strains</b> (page 412) <b>Tendinitis</b> (page 426) <b>Urinary tract infection</b> (page 436)
★☆☆	<b>Angina</b> (page 27) <b>Asthma</b> (page 32) <b>Low back pain</b> (page 293) <b>Rheumatoid arthritis</b> (page 387) Thrombophlebitis

### Who is likely to be deficient?

Since bromelain is not essential, deficiencies of this plant-based **enzyme** (page 506) do not exist.

### How much is usually taken?

Assessing the right amount of bromelain to take is complicated. Most bromelain research was conducted years ago, when amounts used were listed in units of activity that no longer exist. These old units do not precisely convert to new ones. Today, bromelain is measured in MCUs (milk clotting units) or GDUs (gelatin dissolving units). One GDU equals approximately 1.5 MCU. Strong products contain at least 2,000 MCU (1,200–1,333 GDU) per gram (1,000 mg). A supplement containing 500 mg labeled “2,000 MCU per gram” would have 1,000 MCU of activity. Some doctors recommend as much as 3,000 MCU taken three times per day for several days, followed by 2,000 MCU three times per day.<sup>23</sup> Much of the research uses smaller amounts, more like the equivalent of approximately 500 MCU taken four times per day. However, most of the bromelain used in the studies was enteric-coated in order to prevent it from being destroyed by gastric juice. It is likely, therefore, that currently available bromelain preparations (which typically are not enteric-coated) are of lower potency than the bromelain used in most studies.

### Are there any side effects or interactions?

Bromelain is generally safe and free of side effects when taken in moderate amounts. However, one preliminary

report indicates increased heart rate with the use of bromelain.<sup>24</sup> In addition, some people are allergic to bromelain. One woman reportedly developed a hives and severe swelling after taking bromelain, even though she had tolerated bromelain on two other occasions previously.<sup>25</sup> Because bromelain acts as a blood thinner and little is known about how bromelain interacts with blood-thinning drugs, people should avoid combining such drugs with bromelain in order to reduce the theoretical risk of excessive bleeding.

## CALCIUM

**See also:** Calcium: Which Form Is Best? (page 485)

### What is it?

Calcium is the most abundant, essential mineral in the human body. Of the two to three pounds of calcium contained in the average body, 99% is located in the bones and teeth. Calcium is needed to form bones and teeth and is also required for blood clotting, transmission of signals in nerve cells, and muscle contraction. The importance of calcium for preventing **osteoporosis** (page 333) is probably its most well-known role.

Although calcium plays at least some minor role in lowering **blood pressure** (page 246), the mechanisms involved appear complex and somewhat unclear.<sup>1</sup> The level of calcium in the blood is tightly regulated by parathyroid hormone (PTH), and low intake of calcium causes elevations in PTH, which in turn have been implicated in the development of **hypertension** (page 246).<sup>2</sup> High calcium intake has also been associated with a reduced risk of **cardiovascular disease** (page 98) in **postmenopausal** (page 311) women.<sup>3</sup>

By reducing absorption of oxalate,<sup>4</sup> a substance found in many foods, calcium may be able to indirectly reduce the risk of **kidney stones** (page 284).<sup>5</sup> However, people with a history of kidney stones must talk with a doctor before supplementing with calcium because such supplementation might actually *increase* the risk of forming stones for the small number of people who absorb too much calcium.

Calcium also appears to partially bind some fats and cholesterol in the gastrointestinal tract. Perhaps as a result, some research suggests that calcium supplementation may help lower **cholesterol** (page 223) levels.<sup>6</sup>

Animal studies have established a role of calcium in the development of female egg cells (oocytes).<sup>7, 8</sup> Although the precise role of calcium is unclear, some researchers speculate that future studies may identify important uses for calcium in conditions of the human ovary, such as polycystic ovary syndrome (PCOS).<sup>9</sup>

Through a variety of mechanisms, calcium may have **anticancer** (page 87) actions within the colon. Most preliminary studies have shown high calcium diets are associated with reduced **colon cancer** (page 123) risk.<sup>10</sup> Most,<sup>11, 12, 13</sup> but not all,<sup>14</sup> preliminary studies have found taking calcium supplements to also be associated with a reduced risk of colon cancer or precancerous conditions in the colon. One preliminary study reported that high dietary, but not supplemental, calcium intake was associated with a decreased risk of precancerous changes in the colon.<sup>15</sup> In double-blind studies, calcium supplementation has significantly protected against precancerous changes in the colon in some,<sup>16, 17</sup> but not all, studies.<sup>18, 19</sup>

**Warning:** Calcium supplements should be avoided by **prostate cancer** (page 371) patients.

### Where is it found?

Most dietary calcium comes from dairy products. The myth that calcium from dairy products is not absorbed is not supported by scientific research.<sup>20, 21</sup> Other good sources include sardines, canned salmon, green leafy vegetables, and tofu.

**Calcium has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Gestational hypertension</b> (page 202) <b>Lactose intolerance</b> (page 288) (for preventing deficiency if dairy products are avoided only) <b>Osteoporosis</b> (page 333) <b>Preeclampsia</b> (page 361) (for deficiency) <b>Premenstrual syndrome</b> (page 368) <b>Rickets</b> (page 392)
★★☆	<b>Celiac disease</b> (page 102) (for deficiency only) <b>High blood pressure</b> (page 246) <b>High cholesterol</b> (page 223) <b>High triglycerides</b> (page 235) <b>Weight loss</b> (page 446)

Rating	Health Concerns
★☆☆	<b>Amenorrhea</b> (page 22) (calcium for preventing bone loss) <b>Colon cancer</b> (page 123) (reduces risk) <b>Depression</b> (page 145) <b>Dysmenorrhea</b> (page 171) (painful menstruation) <b>Gingivitis (periodontal disease)</b> (page 203) <b>Insulin resistance syndrome</b> (page 273) (Syndrome X) <b>Kidney stones</b> (page 284) <b>Migraine headaches</b> (page 316) <b>Multiple sclerosis</b> (page 323) <b>Pregnancy and postpartum support</b> (page 363)

### Who is likely to be deficient?

Severe deficiency of either calcium or **vitamin D** (page 607) leads to a condition called **rickets** (page 392) in children and **osteomalacia** (page 392) in adults. Since vitamin D is required for calcium absorption, people with conditions causing vitamin D deficiency (e.g., pancreatic insufficiency) may develop a deficiency of calcium as well. Vegans (pure vegetarians), people with dark skin, those who live in northern climates, and people who stay indoors almost all the time are more likely to be vitamin D deficient than are other people. Vegans often eat less calcium and vitamin D than do other people. Most people eat well below the recommended amount of calcium. This lack of dietary calcium is thought to contribute to the risk of **osteoporosis** (page 333), particularly in white and Asian women.

### How much is usually taken?

The National Academy of Sciences has established guidelines for calcium that are 25–50% higher than previous recommendations. For ages 19 to 50, calcium intake is recommended to be 1,000 mg daily; for adults over age 51, the recommendation is 1,200 mg daily.<sup>22</sup> The most common supplemental amount for adults is 800–1,000 mg per day.<sup>23</sup> General recommendations for higher daily intakes (1,200–1,500 mg) usually include the calcium most people consume from their diets. Studies indicate the average daily amount of calcium consumed by Americans is about 500–1,000 mg.

### Are there any side effects or interactions?

**Constipation** (page 137), bloating, and **gas** (page 195) are sometimes reported with the use of calcium supplements.<sup>24</sup> A very high intake of calcium from dairy prod-

ucts plus supplemental calcium carbonate was reported in the past to cause a condition called “milk alkali syndrome.” This toxicity is rarely reported today because most medical doctors no longer tell people with **ulcers** (page 349) to use this approach as treatment for their condition.

People with hyperparathyroidism, chronic kidney disease, or **kidney stones** (page 284) should not supplement with calcium without consulting a physician. For other adults, the highest amount typically suggested by doctors (1,200 mg per day) is considered quite safe. People with **prostate cancer** (page 371) should avoid supplementing with calcium.

In the past, calcium supplements in the forms of bone meal (including MCHC), dolomite, and oyster shell have sometimes had higher lead levels than permitted by stringent California regulations, though generally less than the levels set by the federal government.<sup>25</sup> “Refined” forms (which would include CCM, calcium citrate, and most calcium carbonate) have low levels.<sup>26</sup> More recently, a survey of over-the-counter calcium supplements found low or undetectable levels of lead in most products,<sup>27</sup> representing a sharp decline in lead content of calcium supplements since 1993. People who decide to take bone meal, dolomite, oyster shell, or coral calcium for long periods of time can contact the supplying supplement company to request independent laboratory analysis showing minimal lead levels.

Some studies have shown that calcium competes for absorption with a number of other minerals, while other studies have found no such competition. To be on the safe side, some doctors recommend that people taking calcium for long periods of time should also take a multimineral supplement.

One study has shown that taking calcium can interfere with the absorption of phosphorus, which, like calcium, is important for bone health.<sup>28</sup> Although most western diets contain ample or even excessive amounts of phosphorus, older people who supplement with large amounts of calcium may be at risk of developing phosphorus deficiency. For this reason, the authors of this study recommend that, for elderly people, at least some of the supplemental calcium be taken in the form of tricalcium phosphate or some other phosphorus-containing preparation.

**Vitamin D** (page 607)'s most important role is maintaining blood levels of calcium. Therefore, many doctors recommend that those supplementing with calcium also supplement with 400 IU of vitamin D per day.

Animal studies have shown that essential fatty acids (EFAs) increase calcium absorption from the gut, in part by enhancing the effects of vitamin D and reducing loss of calcium in the urine.<sup>29</sup>

**Lysine** (page 550) supplementation increases the absorption of calcium and may reduce its excretion.<sup>30</sup> As a result, some researchers believe that lysine may eventually be shown to have a role in the prevention and treatment of **osteoporosis** (page 333).<sup>31</sup>

## CALCIUM: WHICH FORM IS BEST?

**See also:** Calcium (page 483)

For adults, dairy products supply 72% of the calcium in the U.S. diet, grain products about 11% and fruits and vegetables about 6%.<sup>1</sup> Milk drinkers get 80% more **calcium** (page 483) in their diet compared to non-milk-drinkers.<sup>2</sup> Apart from total calcium content, foods and supplements should be evaluated in terms of the *bioavailability* of the calcium they contained (i.e., how much of it is actually absorbed and utilized by the body.) Calcium absorption from various dairy products is similar, at about 30%.<sup>3</sup> However, many people choose alternatives to milk and dairy products for health reasons, such as the prevention of **atherosclerosis** (page 38) or food **allergies** (page 14). A variety of calcium-fortified nondairy beverages are now available. However, the bioavailability of calcium in these beverages may differ from that of milk. A study of calcium-fortified soy milk found that the calcium in it was absorbed at only 75% of the efficiency of the calcium in cow's milk.<sup>4</sup> While cow's milk and fortified soy milk are therefore not equivalent as calcium sources, the difference can easily be overcome by either consuming more of the fortified soy beverage, or by consuming soy beverages fortified with proportionally higher amounts of calcium.

Dietary supplements may contain one of several different forms of calcium. One difference between the various calcium compounds is the percentage of elemental calcium present. A greater percentage of elemental calcium means that fewer tablets are needed to achieve the desired calcium intake. For instance, in the calcium carbonate form, calcium accounts for 40% of the compound, while the calcium citrate form provides 24% elemental calcium.

Many medical doctors recommend calcium carbonate because it requires the fewest pills to reach a given level of calcium and it is readily available and inexpensive. For people concerned about cost and only willing to swallow two to three calcium pills per day, calcium carbonate is a sensible choice. Even for these people, however, low-quality calcium carbonate supplements are less than ideal. Depending on how the tablet is manufactured, some calcium carbonate pills have been found to disintegrate and dissolve improperly, which could interfere with absorption.<sup>5</sup> The disintegration of calcium carbonate pills can be easily evaluated by putting a tablet in a half cup of vinegar and stirring occasionally. After half an hour, no undissolved chunks of tablet should remain at the bottom.<sup>6</sup>

Calcium carbonate may not always show optimal absorption, but it clearly has positive effects. For example, calcium carbonate appears to be as well absorbed as the calcium found in milk.<sup>7</sup> In fact, some studies indicate that calcium carbonate is absorbed as well as most other forms besides calcium citrate/malate (CCM).<sup>8,9</sup> For example, a recent study found absorption of calcium from calcium carbonate to be virtually identical to absorption of calcium from calcium citrate.<sup>10</sup>

For people willing to take more pills to achieve a given amount of calcium (typically 800–1,000 mg), calcium carbonate does not appear to be the optimal choice, because other forms have been reported to be absorbed, absorb better (however, they do require more pills per day because each pill contains less calcium). For this reason, some doctors recommend other forms of calcium, particularly CCM. Research shows that CCM is absorbed better than most other forms.<sup>11,12,13</sup> CCM may also be more effective in maintaining bone mass, than some other forms of calcium supplements.<sup>14</sup> Because of their similarity in both name and structure, CCM can be confused with calcium citrate, but they are not the same.

CCM is not the only form of calcium that might be absorbed better than carbonate. For example, most,<sup>15,16</sup> though not all,<sup>17</sup> studies suggest that calcium citrate might have some absorption advantage over calcium carbonate. However, no evidence suggests that calcium citrate is as well absorbed as CCM.

Microcrystalline hydroxyapatite (MCHC), a variation on bonemeal, has attracted attention because of studies reporting increases in bone mass in people with certain conditions<sup>18</sup> and better effects on bone than calcium carbonate.<sup>19</sup> Similar positive studies exist using CCM.<sup>20</sup> However, unlike CCM, MCHC has only oc-

casionally been compared with other forms of calcium. In limited research that does make comparisons, MCHC fared poorly in terms of solubility, absorption, and effect on calcium metabolism.<sup>21, 22</sup>

Remarkably little is known about the relative efficacy of **amino acid** (page 465) chelates (pronounced “keel-lates”) of calcium. In the only commonly cited trial, absorption was measured for an amino acid chelate called calcium bisglycinate and compared with absorption from citrate, carbonate, and MCHC.<sup>23</sup> In that trial, the amino acid chelate showed the best absorption and MCHC the worst. Although CCM was studied in that trial, it was taken under different circumstances than the chelate (with meals), so drawing definitive conclusions is not possible.

Recently, coral calcium has been claimed to be a vastly superior form of calcium, even though its calcium content is primarily calcium carbonate. One small, controlled human study reported that coral calcium was better absorbed than ordinary calcium carbonate.<sup>24</sup> However, the method used in this study to measure calcium absorption has been criticized as much less sensitive than other methods.<sup>25</sup> No research has compared coral calcium to calcium citrate or to CCM. There is little evidence at this time that coral calcium is superior to other forms of calcium.

Whatever the form, calcium supplements typically are absorbed better when eaten with meals.<sup>26</sup> Moreover, research indicates that taking calcium with meals may reduce the risk of **kidney stones** (page 284) and supplementing with calcium between meals might actually increase the risk.<sup>27</sup>

Besides *how* to take calcium supplements, scientists have also been studying *when* to take them. Supplementing calcium in the evening appears better for **osteoporosis** (page 333) prevention than taking calcium in the morning, based on the circadian rhythm of bone loss.<sup>28</sup> In order to not increase the risk of forming **kidney stones** (page 284), most doctors tell people to take calcium supplements only with food.

#### *What is the relationship between calcium supplements and stomach acid?*

Years ago, researchers reported that people who do not make **hydrochloric acid** (page 473) in their stomachs cannot absorb calcium adequately when the calcium is taken alone.<sup>29</sup> In that report, adding hydrochloric acid restored normal calcium absorption. Although researchers have subsequently confirmed these findings, they have also discovered that these same people absorb

calcium normally if they take it with meals. In addition, researchers have noted that giving these people hydrochloric acid does not further improve absorption during meals.<sup>30</sup> Others have confirmed that hydrochloric acid, either from pills or from the stomach, is unnecessary for the absorption of calcium, as long as the calcium supplement is taken with meals.<sup>31, 32, 33, 34</sup>

Some doctors have expressed a concern that antacids that contain calcium (like Tums) or calcium supplements that also act as antacids, interfere with the body's absorption of calcium. However, this is not the case. Calcium carbonate, the principal ingredient in both Tums and many calcium supplements provides significant (though not optimal) absorbable calcium, as discussed above. Other forms of calcium that might be more bio-available, such as calcium citrate, also act as antacids. The form of calcium associated most consistently with best bio-availability, CCM, is itself, an antacid despite the fact it is used almost exclusively as a source of calcium.

Other concerns about the antacid effect of most calcium supplements (particularly when taken by people who do not need and are not seeking an antacid) are voiced by some doctors because stomach acid is needed to protect against bacterial **infection** (page 265) and also to help digest protein. In theory, calcium supplements with antacid activity could at least temporarily interfere with these processes. However, to date, these concerns remain hypothetical.

## CALCIUM D-GLUCARATE

#### **What is it?**

Calcium D-glucarate is the **calcium** (page 483) salt of D-glucaric acid, a natural substance found in many fruits and vegetables.

Calcium D-glucarate has been shown to inhibit beta-glucuronidase, an enzyme found in certain bacteria that reside in the gut. One of the key ways in which the body eliminates toxic chemicals as well as hormones such as estrogen is by attaching glucuronic acid to them in the liver and then excreting this complex in the bile. Beta-glucuronidase is a bacterial enzyme that uncouples (breaks) the bond between the excreted compound and glucuronic acid. When beta-glucuronidase breaks the bond, the hormone or toxic chemical that is released is available to be reabsorbed into the body instead of being excreted. An elevated beta-glucuronidase activity

is associated with an increased risk for various **cancers** (page 87), particularly hormone-dependent cancers like **breast** (page 65), **prostate** (page 371), and **colon** (page 123) cancers.<sup>1</sup>

Studies in animals have shown that supplementing with calcium D-glucarate prevents the development of experimentally induced cancers.<sup>2, 3, 4, 5</sup> The amount of calcium D-glucarate used in these studies, however, would be too much for humans to take. Researchers at M.D. Anderson Cancer Center, Memorial Sloan-Kettering Cancer Center, and other major cancer centers began conducting research with calcium D-glucarate for the prevention and treatment of breast cancer.<sup>6, 7</sup> No human studies showing the efficacy or safety of calcium D-glucarate have been published.

#### Where is it found?

Calcium D-glucarate is available in capsules and tablets. Foods high in glucaric acid (a form of calcium D-glucarate) include apples, Brussels sprouts, broccoli, cabbage, and bean sprouts.<sup>8</sup>

**Calcium D-glucarate has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Cancer (page 87)

#### Who is likely to be deficient?

Calcium D-glucarate is not an essential nutrient, and thus no deficiency state exists.

#### How much is usually taken?

Manufacturers of calcium D-glucarate recommend a daily intake of 200 to 400 mg.

#### Are there any side effects or interactions?

No side effects have been reported with calcium D-glucarate. Although there are no known drug interactions, many drugs (especially hormones) are metabolized in the liver by binding to glucuronic acid. It is therefore possible that taking calcium D-glucarate could increase the elimination of certain drugs or hormones from the body, thereby reducing their effectiveness. If you are taking any prescription medication, please consult your physician or pharmacist before taking calcium D-glucarate.

## CARNOSINE

#### What is it?

Carnosine is a small molecule composed of the **amino acids** (page 465), **histidine** (page 534) and **alanine** (page 463). It is found in relatively high concentrations in several body tissues—most notably in skeletal muscle, heart muscle, and brain.<sup>1, 2</sup>

The exact biological role of carnosine is not completely understood, but numerous animal studies have demonstrated that it possesses strong and specific **antioxidant** (page 467) properties, protects against radiation damage, improves the function of the heart, and promotes **wound healing** (page 319).<sup>3, 4, 5, 6, 7, 8</sup> Carnosine has been suggested to be the water-soluble counterpart to **vitamin E** (page 609) in protecting cell membranes from oxidative damage. Other suggested roles for carnosine include actions as a neurotransmitter (chemical messenger in the nervous system), modulator of enzyme activities, and chelator of heavy metals (i.e., a substance that binds heavy metals, possibly reducing their toxicity).

Based primarily on preliminary research from Russia, carnosine has been claimed to lower **blood pressure** (page 246), improve the functioning of the **immune system** (page 255), promote **wound healing** (page 319), and exert **anticancer** (page 87) effects. However, additional research is needed before these claims can be considered scientifically well documented.

The best-documented application of carnosine is in **peptic ulcers** (page 349). Experimental animal studies have shown that a zinc salt of carnosine exerts significant protection against ulcer formation and promotes the healing of existing ulcers.<sup>9, 10</sup> However, because **zinc** (page 614) by itself has been shown to be helpful against peptic ulcer, it is not known how much of the beneficial effect was due to the carnosine.<sup>11, 12</sup> Clinical studies in humans demonstrated that this compound can help eradicate *Helicobacter pylori*, an organism that has been linked to peptic ulcer and stomach **cancer** (page 87).<sup>13</sup> When 60 patients suffering from dyspepsia with *H. pylori* **infection** (page 265) were given either antibiotics alone (lansoprazole, amoxicillin, and clarithromycin) or antibiotics plus zinc carnosine for seven days, better results were seen in the group receiving zinc carnosine (94% eradication rate vs. 77%). The zinc salt of carnosine (in combination with sodium alginate) has also shown to be effective in severe **gingivitis** (page 203) caused by cancer chemotherapy.<sup>14</sup>

In a preliminary trial, supplementation with a zinc salt of carnosine enhanced the response to interferon therapy in patients with chronic hepatitis C.<sup>15</sup> It is not known whether this benefit was due primarily to the zinc or the carnosine, or whether other forms of carnosine would have the same effect.

### Where is it found?

Dietary sources of preformed carnosine include meat and poultry and fish.

**Carnosine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Hepatitis C</b> (page 220) ( <b>zinc</b> [page 614]-L-carnosine)
★☆☆	<b>Peptic ulcers</b> (page 349) <b>Wound healing</b> (page 357)

### Who is likely to be deficient?

Carnosine deficiency may occur in severe protein deficiency and in certain severe genetic disorders characterized by inborn errors in **amino acid** (page 465) metabolism.

### How much is usually taken?

For eradication of *H. pylori*, the amount of the **zinc** (page 614) carnosine complex used in research studies was 150 mg twice daily. Due to the lack of human clinical trials, recommended levels for other applications are not known at this time.

### Are there any side effects or interactions?

Due to the lack of human studies, side effects and interactions are not known.

## CAROTENOIDS

### What are they?

Carotenoids are a highly colored (red, orange, and yellow) group of fat-soluble plant pigments. All organisms, whether bacteria or plants, that rely on the sun for energy contain carotenoids. Their **antioxidant** (page 467) effects enable these compounds to play a crucial role in protecting organisms against damage during

photosynthesis—the process of converting sunlight into chemical energy.

In humans, carotenoids play two primary roles: All exert antioxidant activity, but some are also converted into **vitamin A** (page 595). Of the 600 carotenoids that have been identified, about 30 to 50 are believed to have vitamin A activity. Carotenoids the body converts to vitamin A are referred to as “provitamin A” carotenoids. The most well known of this group are **beta-carotene** (page 469) and alpha-carotene. Some of the better known carotenoids without provitamin A activity—but with very high antioxidant activity—are **lutein** (page 548), **lycopene** (page 548), and zeaxanthin.<sup>1, 2</sup>

Preliminary and experimental studies suggest that a higher dietary intake of carotenoids offers protection against developing certain **cancers** (page 87) (e.g., lung, skin, uterine, cervix, gastrointestinal tract), **macular degeneration** (page 303), **cataracts** (page 101), and other health conditions linked to oxidative or **free radical** (page 467) damage.<sup>3, 4, 5, 6</sup> However, two double-blind studies have shown that supplementation with isolated synthetic beta-carotene does not reduce the risk of **lung cancer** (page 298) and may even increase that risk in smokers.<sup>7, 8</sup> This finding suggests that foods that are high in carotenoids may protect against cancer in humans for reasons unrelated to their carotenoid content, that synthetic beta-carotene may have different effects from natural beta-carotene (which is somewhat structurally distinct), or that carotenoids may need to be taken together or with supportive antioxidants (e.g., **vitamin C** [page 604], **vitamin E** [page 609], **selenium** [page 584]) in order to reduce the risk of cancer. Researchers have yet to determine which of these possibilities is true.

A high intake of carotenoids from dietary sources has been shown to be protective against **heart disease** (page 98) in several population-based studies.<sup>9, 10</sup> However, a high level of these antioxidants might simply be a marker for diets high in fruits and vegetables known to contain protective substances other than carotenoids. Furthermore, a diet rich in carotenoids tends to be lower in saturated fat and **cholesterol** (page 223) and higher in **fiber** (page 512), which has also found to be protective against heart disease.

Because of their **antioxidant** (page 467) activity, it has been suggested that **beta-carotene** (page 469) and other carotenoids might protect against **atherosclerosis** (page 38) by preventing oxidative damage to serum cholesterol. However, research is conflicting in this

area. One thing is clear—carotenoids are significantly less effective in protecting against damage to serum cholesterol than is **vitamin E** (page 609). While feeding people beta-carotene has been shown to prevent oxidative damage to cholesterol in some trials,<sup>11</sup> other studies have reported that beta-carotene does not protect cholesterol from oxidative damage.<sup>12, 13</sup>

Just as in the case of cancer prevention, while a high intake of carotenoid-rich foods appears to be protective against cardiovascular disease, the same is not true for supplementation with synthetic beta-carotene. Double-blind intervention trials wherein people are supplemented with beta-carotene alone or placebo have not found benefit for synthetic beta-carotene supplementation. In fact, three of four trials have reported a *higher* risk of **cardiovascular disease** (page 98) in the beta-carotene groups compared with those receiving placebo.<sup>14, 15, 16, 17</sup> While these outcomes prove that synthetic beta-carotene does not protect against heart disease, the effects of natural beta-carotene and other carotenoids have yet to be tested in intervention trials assessing effects on heart disease.

A potential problem with much of the research on carotenoids in cardiovascular disease has been the focus on beta-carotene. A preliminary study found a strong association between dietary sources of **lycopene** (page 548), not beta-carotene, and reduced risk of **heart attacks** (page 98).<sup>18</sup> Lycopene exerts greater antioxidant activity compared to beta-carotene, and lycopene has also been reported to protect cholesterol against oxidative damage.<sup>19</sup>

### Where are they found?

Carotenoids are found in all plant foods. In general, the greater the intensity of color, the higher the level of carotenoids. In green leafy vegetables, **beta-carotene** (page 469) is the predominant carotenoid. In the orange colored fruits and vegetables—such as carrots, apricots, mangoes, yams, winter squash—beta-carotene concentrations are high, but other pro-vitamin A carotenoids typically predominate. Yellow vegetables have higher concentrations of yellow carotenoids (xanthophylls), hence a lowered pro-vitamin A activity; but some of these compounds, such as **lutein** (page 548), may have significant health benefits, potentially due to their **antioxidant** (page 467) effects. The red and purple vegetables and fruits—such as tomatoes, red cabbage, berries, and plums—contain a large portion of non-vitamin A-active carotenoids. Legumes, grains, and seeds are also significant sources of carotenoids.

Carotenoids are also found in various animal foods, such as salmon, egg yolks, shellfish, milk, and poultry. A variety of carotenoids is also found in carrot juice and “green drinks” made from vegetables, dehydrated barley greens, or wheat grass.

Synthetic beta-carotene is available as a supplement. Mixed carotenoids (including the natural form of beta-carotene) are also available in supplements derived from palm oil, algae, and carrot oil.

**Carotenoids have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Cataracts</b> (page 101) (prevention) <b>Heart disease</b> (page 98) (prevention) <b>Macular degeneration</b> (page 303) (prevention) ( <b>lutein</b> [page 548], <b>zeaxanthin</b> , <b>lycopene</b> [page 548]) <b>Sickle cell anemia</b> (page 403)

### Who is likely to be deficient?

Carotenoid deficiency is not considered a classic nutritional deficiency like scurvy or beri-beri (severe **vitamin C** [page 604] and **vitamin B<sub>1</sub>** [page 597] deficiencies, respectively). However, given the possible health benefits of carotenoids, most doctors recommend adequate intake. People who do not frequently consume carotenoid-rich foods or take carotenoid supplements are likely to be taking in less than adequate amounts, though optimal levels remain unknown. Also, deficiency may be found in people with chronic **diarrhea** (page 163) or other disorders associated with impaired absorption.

### How much is usually taken?

Whether people who already consume a diet high in fruits and vegetables would benefit further from supplementation with a mixture of carotenoids remains unknown. While smokers clearly should not supplement with isolated synthetic **beta-carotene** (page 469), the effect in smokers of taking either natural beta-carotene or mixed carotenoids is not clear.

Nonetheless, based on health-promoting effects associated with these levels in preliminary research, some doctors recommend that most people supplement with up to 25,000 IU (15 mg) per day of natural beta-carotene and approximately 6 mg each of alpha-carotene, **lutein** (page 548), and **lycopene** (page 548).

### Are there any side effects or interactions?

Carotenoids are generally regarded as safe, based primarily on studies with **beta-carotene** (page 469). Increased consumption of carotenoids may cause the skin to turn orange or yellow—a condition known as “carotenodermia.” This occurrence is completely benign and is unrelated to jaundice—the yellowing of the skin that can result from liver disease or other causes.

Until more is known, people especially smokers should not supplement with synthetic beta-carotene. Two double-blind studies have shown that supplementation with isolated synthetic beta-carotene may increase the risk of **lung cancer** (page 298) in people who smoke.<sup>20, 21</sup> Moreover, three of four studies have found small increases in the risk of **heart disease** (page 98) in people assigned to take synthetic beta-carotene compared with those assigned to take placebo.<sup>22, 23, 24, 25</sup>

### Who is likely to be deficient?

Since they are not essential nutrients, neither cartilage nor collagen are associated with deficiencies.

### How much is usually taken?

Bovine cartilage is typically recommended at 3 grams three times per day. Shark cartilage is sometimes taken in much higher amounts (e.g., 60 to 100 grams per day orally or by enema). These amounts are based on animal and anecdotal evidence and their safety and efficacy have not been confirmed by controlled clinical trials. Not only is toxicity information on this amount of shark cartilage lacking, but the amount of calcium in this amount of shark cartilage exceeds the 2 to 2.5 grams per day that is commonly considered to be the upper limit of safe intake. Type II collagen, when used for its effects on the immune system in rheumatoid arthritis, is used in very small amounts, from 0.02 mg to 10 mg per day. Gelatin and collagen hydrolysate is recommended at 7 to 10 grams per day.

## CARTILAGE AND COLLAGEN

### What is it?

Cartilage, derived from shark, bovine (cow), and other animal sources, is a type of connective tissue composed of mucopolysaccharides (including **chondroitin sulfate** [page 492]), protein substances, **calcium** (page 483), **sulfur** (page 590), and collagen. Collagen is one of the proteins found in most connective tissues, including cartilage, bone, and skin. Gelatin is a form of collagen commonly used in foods, and preliminary reports suggest that consuming gelatin can improve the structure and health of the hair and nails.<sup>1, 2, 3, 4</sup> Collagen hydrolysate is produced by enzymatically breaking down bovine gelatin to smaller protein fragments.

### Where is it found?

Cartilage is derived from either sharks or cows. Collagen is derived from either cows or chickens.

**Cartilage and collagen have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Osteoarthritis</b> (page 328)
★★★	Karposi's sarcoma (skin cancer)
	<b>Prostate cancer</b> (page 371) (shark cartilage)

### Are there any side effects or interactions?

Reports have suggested that some people should not use a cartilage supplement. This concern is based only on theory, not clinical evidence. This would include those people with **cardiovascular disease** (page 98), women who are planning to be or are **pregnant** (page 363), nursing mothers, anyone having or having had surgery within 30 days, and **athletes** (page 43) training intensely. None of these concerns have been proven in clinical trials, however. Because shark cartilage contains **calcium** (page 483), people who ingest large amounts of shark cartilage (60 to 100 grams per day) may be consuming excessive amounts of this mineral. However, no cases of calcium toxicity resulting from the ingestion of shark cartilage have been reported.

While use of gelatin, collagen hydrolysate, or type II collagen has not resulted in any reports of serious side effects, people with known sensitivities to chicken or beef should consult a doctor before using them.

## CETYL MYRISTOLEATE

### What is it?

Cetyl myristoleate (CMO) is the common name for cis-9-cetyl myristoleate. CMO was discovered in 1972 by Harry W. Diehl, Ph.D., a researcher at the National Institutes of Health. At the time, Dr. Diehl was respon-

sible for testing anti-inflammatory drugs on lab animals. In order for him to test the drugs, he first had to artificially induce arthritis in the animals by injecting a heat-killed bacterium called Freund's adjuvant. Dr. Diehl discovered that Swiss albino mice did not get arthritis after injection of Freund's adjuvant. Eventually, he was able to determine that cetyl myristoleate was the factor present naturally in mice that was responsible for this protection. When CMO was injected into various strains of rats, it offered the same protection against arthritis.<sup>1</sup>

It has been proposed that CMO acts as a joint "lubricant" and anti-inflammatory agent. Patents were granted to Dr. Diehl for the use of CMO in both **osteoarthritis** (page 328) and **rheumatoid arthritis** (page 387), based upon the animal studies and several case histories.<sup>2, 3, 4</sup> In a double-blind study, 106 people with various types of arthritis who had failed to respond to nonsteroidal anti-inflammatory drugs (NSAIDs) received cetyl myristoleate (540 mg per day orally for 30 days), while 226 others received a placebo. These people also applied cetyl myristoleate or placebo topically, according to their perceived need. Some 63.5% of those receiving cetyl myristoleate improved, compared with only 14.5% of those receiving the placebo (a statistically significant difference).<sup>5</sup>

#### Where is it found?

Cetyl myristoleate is found in certain animals, including cows, whales, beavers, and mice. As a nutritional supplement it is found in a highly purified, refined form in capsules and tablets. CMO is also available in creams and lotions for topical application.

#### CMO has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Osteoarthritis (page 328) Rheumatoid arthritis (page 387)

#### Who is likely to be deficient?

As cetyl myristoleate is not an essential nutrient, no deficiency state exists.

#### How much is usually taken?

Generally, CMO is taken in the amount of 400 to 500 mg daily for 30 days.

#### Are there any side effects or interactions?

No side effects or drug interactions have been reported.

## CHITOSAN

#### What is it?

Chitosan is a polysaccharide found in the shells of crustaceans.

Like dietary **fiber** (page 512), chitosan is not digestible but may have beneficial effects on the gastrointestinal tract. Chitosan may also have an effect on the type of bacteria living in the intestines or on the action of these bacteria.

#### Where is it found?

Chitosan is extracted from the shells of crustaceans, such as shrimp and crab.

#### Chitosan has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	High cholesterol (page 223) Kidney failure Weight loss (page 446)

#### Who is likely to be deficient?

Chitosan is not an essential nutrient, so deficiencies do not occur.

#### How much is usually taken?

Most human research has used 3–6 grams per day with meals.

#### Are there any side effects or interactions?

While no long-term studies of the effects of chitosan on human health have been done, animal studies suggest that this compound could inhibit the absorption of **minerals** (page 559) and fat-soluble **vitamins** (page 559). Adverse effects on the growth of children and on the outcome of **pregnancy** (page 363) are also possible.<sup>1</sup> In addition, although chitosan-included alterations in intestinal flora are believed to be beneficial, the possibility that these changes may have negative long-term consequences has not been ruled out. People

with **intestinal malabsorption** (page 304) syndromes should not use chitosan.

## CHLOROPHYLL

### What is it?

Chlorophyll is the substance responsible for the green color in plants that accomplishes photosynthesis.

Chlorophyll has been used traditionally to improve bad breath, as well as to reduce the odors of urine, feces, and infected wounds. Chlorophyll has anti-inflammatory, **antioxidant** (page 467), and **wound-healing** (page 319) properties.<sup>1,2</sup>

Historically, chlorophyll was used for gastrointestinal problems, such as **constipation** (page 137), and to stimulate blood cell formation in **anemia** (page 25). Some preliminary evidence suggests that chlorophyll might help detoxify **cancer** (page 87)—promoting substances.<sup>3,4</sup>

### Where is it found?

Good dietary sources of chlorophyll include dark green leafy vegetables, algae (including **spirulina** [page 474] and chlorella), wheat grass, and barley grass. Supplements of chlorophyll as powder, capsules, tablets, and drinks are also available.

**Chlorophyll has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Fibromyalgia</b> (page 191)
★★★	<b>Constipation</b> (page 137)
	<b>Halitosis</b> (page 209) (bad breath)

### Who is likely to be deficient?

Because chlorophyll is not known to be an essential nutrient, a deficiency does not exist. People who do not eat plenty of green foods lack chlorophyll in their diets.

### How much is usually taken?

Optimal levels remain unknown. Chlorophyll in the amount of 100 mg two or three times per day can be used to treat **bad breath** (page 209).

### Are there any side effects or interactions?

No side effects have been reported with the use of chlorophyll.

## CHONDROITIN SULFATE

### What is it?

Chondroitin sulfate consists of repeating chains of molecules called glycosaminoglycans (GAGs). Chondroitin sulfate is a major constituent of **cartilage** (page 490), providing structure, holding water and nutrients, and allowing other molecules to move through cartilage—an important property, as there is no blood supply to cartilage.

In degenerative joint disease, such as **osteoarthritis** (page 328), there is a loss of chondroitin sulfate as the cartilage erodes. Animal studies indicate that chondroitin sulfate may promote healing of bone, which is consistent with the fact that the majority of glycosaminoglycans found in bone consist of chondroitin sulfate.<sup>1</sup> Chondroitin sulfate has been shown, in numerous double-blind trials,<sup>2, 3, 4, 5, 6, 7, 8, 9</sup> to relieve symptoms and possibly slow the progression of, or reverse, osteoarthritis.<sup>10</sup>

Chondroitin and similar compounds are present in the lining of blood vessels and the urinary bladder. They help prevent abnormal movement of blood, urine, or components across the barrier of the vessel or bladder wall. Part of chondroitin's role in blood vessels is to prevent excessive blood clotting. However, whether supplements of chondroitin are able to favorably affect blood clotting remains unclear. In addition, chondroitin sulfate may lower blood **cholesterol levels** (page 223).<sup>11</sup> Older preliminary research showed that chondroitin sulfate may prevent **atherosclerosis** (page 38) in animals and humans and may also prevent **heart attacks** (page 212) in people who already have atherosclerosis.<sup>12, 13, 14</sup>

Chondroitin sulfate can help form a coating on nasal passages. Perhaps as a result, researchers found that when chondroitin sulfate was sprayed into the nasal passages of a small group of people who snore, the amount of time people spent snoring was reduced about one-third in a double-blind trial.<sup>15</sup> No further studies have investigated the effects of oral chondroitin sulfate on snoring.

Chondroitin sulfate is rich in **sulfur** (page 590) and is related to **glucosamine** (page 528). GAGs affect how

the body processes oxalate—a substance linked to **kidney stones** (page 284). In one study of 40 people with a history of kidney stones, 30 mg twice a day of mixed GAGs reduced urinary oxalate excretion in 15 days—a change that could drop the risk of stone formation.<sup>16</sup> However, studies on the effect of GAGs on stone formation in humans have produced inconsistent results.<sup>17</sup>

### Where is it found?

The only significant food source of chondroitin sulfate is animal **cartilage** (page 490).

**Chondroitin sulfate has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Osteoarthritis</b> (page 327)
★★☆	<b>Wound healing</b> (page 319) (topical)
★☆☆	<b>Atherosclerosis</b> (page 38) <b>Heart attack</b> (page 212) <b>High cholesterol</b> (page 223) <b>Kidney stones</b> (page 284) <b>Sprains and strains</b> (page 412) <b>Wound healing</b> (page 319) (oral)

### Who is likely to be deficient?

Because the body makes chondroitin, the possibility of a dietary deficiency remains uncertain. Nevertheless, chondroitin sulfate may be reduced in joint **cartilage** (page 490) affected by **osteoarthritis** (page 328) and possibly other forms of arthritis.

### How much is usually taken?

For **atherosclerosis** (page 38), researchers have sometimes started therapy using very high amounts, such as 5 grams twice per day with meals, lowering the amount to 500 mg three times per day after a few months. Before taking such high amounts, people should consult a doctor. For **osteoarthritis** (page 328), a typical level is 400 mg three times per day. Oral chondroitin sulfate is rapidly absorbed in humans when it is dissolved in water prior to ingestion. Approximately 12% of chondroitin sulfate taken by mouth becomes available to the joint tissues from the blood.<sup>18</sup>

### Are there any side effects or interactions?

Nausea may occur at intakes greater than 10 grams per day. No other adverse effects have been reported.

One doctor has raised a concern that chondroitin sulfate should not be used by men with **prostate cancer** (page 371). This concern is based upon two studies. In one, the concentration of chondroitin sulfate was found to be higher in cancerous prostate tissue as compared to normal prostate tissue.<sup>19</sup> In the other study, it was shown that higher concentrations of chondroitin sulfate in the tissue surrounding a cancerous prostate tumor predict a higher rate of recurrence of the **cancer** (page 87) after surgery.<sup>20</sup> However, no studies to date have addressed the question of whether taking chondroitin sulfate supplements could promote the development of prostate cancer. Simply because a substance is present in or around cancerous tissue does not by itself suggest that that substance is causing the cancer. For example, **calcium** (page 483) is a component of atherosclerotic plaques that harden the arteries; however, there is no evidence that taking calcium supplements causes atherosclerosis. To provide meaningful information, further studies would need to track the incidence of prostate cancer in men taking chondroitin supplements. Until then, most nutritionally-oriented doctors remain unconcerned about this issue.

It is not known whether taking **glucosamine sulfate** (page 529) and chondroitin sulfate in combination is a more effective treatment for **osteoarthritis** (page 328) than taking either one by itself.

## CHROMIUM

### What is it?

Chromium is an essential trace mineral that helps the body maintain normal blood sugar levels.

In addition to its well-studied effects in **diabetes** (page 152), preliminary research has found that chromium supplementation also improves glucose tolerance in people with Turner's syndrome—a disease linked with glucose intolerance.<sup>1</sup>

Chromium may also play a role in increasing HDL ("good") cholesterol,<sup>2</sup> while lowering total **cholesterol levels** (page 223).<sup>3</sup>

Chromium, in a form called chromium picolinate, has been studied for its potential role in altering body composition. Preliminary research in animals<sup>4</sup> and humans<sup>5, 6</sup> suggested that chromium picolinate increases fat loss and promotes a gain in lean muscle tissue. Double-blind research has also reported a reduction in body fat<sup>7</sup> and body weight<sup>8</sup> in people given 400 mcg of

chromium (as chromium picolinate) per day for three months. However, other studies have failed to show a significant effect of chromium picolinate on body composition.<sup>9</sup>

### Where is it found?

The best source of chromium is true **brewer's yeast** (page 480). Nutritional yeast and torula yeast do not contain significant amounts of chromium and are not suitable substitutes for brewer's yeast. Chromium is also found in grains and cereals, though much of it is lost when these foods are refined. Some brands of beer contain significant amounts of chromium.

**Chromium has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Diabetes</b> (page 152) <b>High cholesterol</b> (page 223) <b>Hypoglycemia</b> (page 251)
★★☆	<b>High triglycerides</b> (page 235) <b>Insulin resistance syndrome</b> (page 273) (Syndrome X)
★☆☆	<b>Athletic performance</b> (page 43) <b>Depression</b> (page 145) <b>Weight loss</b> (page 446)

### Who is likely to be deficient?

Most people eat less than the U.S. National Academy of Science's recommended range of 50–200 mcg per day. The high incidence of adult-onset **diabetes** (page 152) suggests to some doctors that many people should be supplementing with small amounts of chromium.

### How much is usually taken?

A daily intake of 200 mcg is recommended by many doctors.

### Are there any side effects or interactions?

In supplemental amounts (typically 50–300 mcg per day), chromium has not been found to cause toxicity in humans. While there are a few reports of people developing medical problems while taking chromium, a cause-effect relationship was not proven. One study suggested that chromium in very high concentrations in a test tube could cause chromosomal mutations in

ovarian cells of hamsters.<sup>10,11</sup> Chromium picolinate can be altered by **antioxidants** (page 467) or hydrogen peroxide in the body to a form that could itself create free radical damage.<sup>12</sup> In theory, these changes could increase the risk of **cancer** (page 87), but so far, chromium intake has not been linked to increased incidence of cancer in humans.<sup>13</sup>

Chromium supplementation may enhance the effects of drugs for **diabetes** (page 152) (e.g., insulin, blood sugar-lowering agents) and possibly lead to **hypoglycemia** (page 251). Therefore, people with diabetes taking these medications should supplement with chromium only under the supervision of a doctor.

One report of severe illness (including **liver** (page 290) and **kidney** (page 284) damage) occurring in a person who was taking 1,000 mcg of chromium per day has been reported.<sup>14</sup> However, chromium supplementation was not proven to be the cause of these problems. Another source claimed that there have been reports of mild **heart rhythm abnormalities** (page 93) with excessive chromium ingestion.<sup>15</sup> However, no published evidence supports this assertion.

Three single, unrelated cases of toxicity have been reported from use of chromium picolinate. A case of kidney failure appeared after taking 600 mcg per day for six weeks.<sup>16</sup> A case of anemia, liver dysfunction, and other problems appeared after four to five months of 1,200–2,400 mcg per day.<sup>17</sup> A case of a muscle disease known as rhabdomyolysis appeared in a body builder who took 1200 mcg over 48 hours.<sup>18</sup> Whether these problems were caused by chromium picolinate or, if so, whether other forms of chromium might have the same effects at these high amounts remains unclear. No one should take more than 300 mcg per day of chromium without the supervision of a doctor.

Preliminary research has found that **vitamin C** (page 604) increases the absorption of chromium.<sup>19</sup>

## COCONUT OIL

### What is it?

Coconut oil is a member of the family of tropical oils, which also include palm, palm kernel, cocoa, and shea nut oils. These oils have been used for centuries in the traditional diets of people living in tropical regions such as the Polynesian islands. Because these populations ex-

perience less of the diseases, such as **heart disease** (page 98), that are common in Western countries, some people believe that tropical oils such as coconut oil, especially in their natural state, can be part of a healthful diet.<sup>1, 2</sup> Currently, these oils are used in Western countries in small amounts, primarily in the production of processed foods.

Tropical oils are high in saturated fat, which has been associated with increased risk of **high blood cholesterol** (page 223), **atherosclerosis** (page 38), and heart disease.<sup>3, 4, 5</sup> However, saturated fat is not a single substance but rather a family of molecules having varying lengths, and coconut oil has more of the shorter-length type of saturated fat molecules (known as lauric acid and myristic acid) compared with most animal fats.<sup>6</sup> This has led to speculation that coconut oil might have different effects on cholesterol levels and heart disease risk compared with other sources of saturated fats. Most controlled human studies, however, find significant cholesterol-raising effects of diets high in either myristic acid,<sup>7, 8, 9</sup> lauric acid,<sup>10, 11</sup> or a combination of these two fatty acids,<sup>12</sup> although this increase is usually a combination of both higher low-density lipoprotein (LDL; “bad”) and high-density lipoprotein (HDL; “good”) cholesterol.

Whether consuming coconut oil will result in unhealthy changes to blood cholesterol levels is controversial. In a double-blind study of young men with normal cholesterol levels, coconut oil was used to create a diet higher in both myristic and lauric acids, and this diet was compared with a similar diet with longer-chain saturated fatty acids. The coconut oil diet resulted in higher levels of both total and LDL cholesterol, whereas HDL levels were not significantly different.<sup>13</sup> Most other controlled studies of healthy young adults have reported that coconut oil increases both LDL and HDL compared with either beef fat, palm oil, or vegetable oils high in unsaturated fats.<sup>14, 15, 16, 17</sup> A controlled study of Polynesians found that a diet with coconut oil resulted in lower LDL levels compared with butter, while HDL was not different between the two diets.<sup>18</sup> However, one trial found no difference in the effects on cholesterol levels of a diet containing small amounts (4% of total calorie intake) of coconut oil compared with similar diets containing other fat sources.<sup>19</sup> More research is needed to determine whether consuming coconut oil will affect the risk of atherosclerosis and heart disease.

Animal studies suggest that coconut oil can affect en-

ergy and fat metabolism in a way that could improve the results of a **weight-loss** (page 446) diet.<sup>20</sup> In a two-week double-blind trial investigating the effect of dietary fat on fat metabolism, a diet containing shorter-chain saturated fatty acids from coconut oil and butter was compared with one containing longer-chain saturated fatty acids from beef fat.<sup>21</sup> The coconut oil-butter diet led to changes in fat metabolism that suggested that eating these fats might result in better control of body weight. However, no studies have investigated whether consuming coconut oil actually affects body weight.

According to test tube studies, some of the fatty acids present in coconut oil have antibacterial,<sup>22, 23, 24</sup> antiviral,<sup>25, 26, 27, 28</sup> and **immune system** (page 255)-stimulating effects,<sup>29</sup> suggesting that coconut oil might be helpful in fighting infections. However, no research has investigated these possible effects in humans.

Synthetic fats resembling those found in coconut oil have been found to have anticancer effects in animals but whether these effects would be possible in humans consuming coconut oil is unknown.<sup>30, 31</sup>

## Coconut Oil

### Where is it found?

Coconut oil may be found in many types of processed foods, including fried foods, crackers, desserts, candies, whipped topping, and non-dairy creamers. It is also available in some grocery stores for use in cooking.

### Who is likely to be deficient?

There is no human requirement for coconut oil or the shorter-length fatty acids it contains, so no deficiency is possible.

### How much is usually taken?

The traditional diets of Pacific Islanders contain several grams per day or more of lauric acid from coconut products, which would require at least one tablespoon per day of coconut oil. Research has not established a recommended intake for coconut oil.

### Are there any side effects or interactions?

Serious allergic reactions to coconut or coconut oil have been reported but are considered rare.<sup>32, 33, 34</sup>

People using large amounts of coconut oil in their diet should have their blood cholesterol levels checked regularly.

## COENZYME Q<sub>10</sub>

### What is it?

Coenzyme Q<sub>10</sub> (CoQ<sub>10</sub>) is also called ubiquinone, a name that signifies its ubiquitous (widespread) distribution in the human body. CoQ<sub>10</sub> is used by the body to transform food into adenosine triphosphate (ATP), the energy on which the body runs.

CoQ<sub>10</sub> is a powerful **antioxidant** (page 467) that protects the body from free radicals<sup>1</sup> and helps preserve **vitamin E** (page 609), the major antioxidant of cell membranes and blood cholesterol.<sup>2</sup>

CoQ<sub>10</sub> supplementation has been investigated as a way to improve physical endurance because of its effect on energy production; however, most research shows that CoQ<sub>10</sub> does not improve **athletic performance** (page 43).<sup>3</sup> In other research, investigators reported no differences in CoQ<sub>10</sub> in muscles or blood from patients with **fibromyalgia** (page 191) compared with healthy people.<sup>4</sup>

Synthesis of sperm requires considerable energy. Due to its role in energy production, CoQ<sub>10</sub> has been studied in **infertile men** (page 305). Preliminary research reports that supplementation of CoQ<sub>7</sub>, a related molecule, increased sperm counts in a group of infertile men.<sup>5</sup>

Healing of the gums of the mouth (periodontal tissue) may require increased energy production; therefore, researchers have explored the effects of CoQ<sub>10</sub> supplementation in people with **periodontal disease** (page 203), which has been linked to CoQ<sub>10</sub> deficiency. Double-blind research shows that people with gum disease given CoQ<sub>10</sub> achieve better results than those given a placebo.<sup>6</sup>

The role of CoQ<sub>10</sub> in energy formation also relates to how the body uses carbohydrates. Preliminary research suggests that a close relative of this nutrient lowered blood sugar levels in a group of people with **diabetes** (page 152).<sup>7</sup> People with type 2 (adult onset) diabetes have been found to have significantly lower blood levels of CoQ<sub>10</sub> compared with healthy people.<sup>8</sup>

Virtually every cell of the human body contains CoQ<sub>10</sub>. It is concentrated in the mitochondria, the area of cells where energy is produced. The heart and liver contain the greatest amount of CoQ<sub>10</sub>. It has helped some people with **congestive heart failure** (page 134), (CHF)<sup>9</sup> an effect reported in an analysis of eight controlled trials<sup>10</sup> and found in some,<sup>11</sup> though not all, double-blind studies.<sup>12, 13, 14</sup> The beneficial effects of

CoQ<sub>10</sub> may not be seen until after several months of treatment. Discontinuation of CoQ<sub>10</sub> supplementation in people with CHF has resulted in severe relapses and should only be attempted under the supervision of a doctor.<sup>15</sup>

Similar improvements have been reported in people with **cardiomyopathies** (page 95)—a group of diseases affecting heart muscle. Research (including double-blind studies) in this area has been consistently positive.<sup>16</sup>

Also, due to its effect on heart muscle, researchers have studied CoQ<sub>10</sub> in people with **heart arrhythmias** (page 93). Preliminary research in this area reported improvement after approximately one month in people with premature ventricular beats (a form of arrhythmia) who also suffer from **diabetes** (page 152).<sup>17</sup>

**Angina** (page 27) patients taking 150 mg per day of CoQ<sub>10</sub> report a greater ability to exercise without experiencing chest pain.<sup>18</sup> This has been confirmed in independent investigations.<sup>19</sup>

CoQ<sub>10</sub> appears to increase the heart's tolerance to a lack of oxygen. Perhaps as a result, preliminary research has shown that problems resulting from heart surgery occurred less frequently in people given CoQ<sub>10</sub> compared with the control group.<sup>20</sup>

Muscle mitochondria lack adequate CoQ<sub>10</sub> in people with muscular dystrophy, a problem that could affect muscle function. In a double-blind three-month trial, four of eight people with muscular dystrophy had improvements in heart function and sense of well-being when supplementing CoQ<sub>10</sub>.<sup>21</sup>

Mitochondrial function also appears to be impaired in people with **Alzheimer's disease** (page 19). Due to CoQ<sub>10</sub>'s effects on mitochondrial functioning, one group of researchers has given CoQ<sub>10</sub> (along with **iron** [page 540] and **vitamin B<sub>6</sub>** [page 601]) to several people with Alzheimer's disease and reported the progression of the disease appeared to have been prevented for one and a half to two years.<sup>22</sup>

CoQ<sub>10</sub> also modulates **immunity** (page 255).<sup>23</sup> Perhaps as a result, a few cases have been reported in which women with metastatic **breast cancer** (page 65) (cancer that had spread to other tissues) had a regression of their **cancer** (page 87) after treatment with a very large amount of CoQ<sub>10</sub> (390 mg per day).<sup>24</sup>

CoQ<sub>10</sub> appears to modulate blood pressure by reducing resistance to blood flow.<sup>25</sup> Several trials have reported that supplementation with CoQ<sub>10</sub> significantly reduced blood pressure in people with **hypertension** (page 246), usually after ten weeks to four or more months of treatment.<sup>26</sup>

In a double-blind study of 21 patients with chronic renal (kidney) failure, 15 of whom were on dialysis, supplementation with 60 mg of CoQ<sub>10</sub> three times per day for four weeks improved certain measures of kidney function (BUN [blood urea nitrogen], serum creatinine, and creatinine clearance), compared with placebo, and eliminated the need for dialysis in some patients.<sup>27</sup> Because chronic renal failure is a serious and complicated disease, individuals with this condition should take CoQ<sub>10</sub> only under strict medical supervision.

In a double-blind trial, administration of 1,200 mg of CoQ<sub>10</sub> per day for 16 months to people with early Parkinson's disease significantly slowed the progression of the disease, compared with a placebo.<sup>28</sup> Smaller amount of CoQ<sub>10</sub> were slightly more effective than placebo, but the difference was not statistically significant.

#### Where is it found?

CoQ<sub>10</sub> is found primarily in fish and meat, but the amounts in food are far less than what can be obtained from supplements.

**Coenzyme Q<sub>10</sub> has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Angina</b> (page 27) <b>Heart attack</b> (page 212) <b>High blood pressure</b> (page 246)
★★☆	<b>Cardiomyopathy</b> (page 95) Cerebellar ataxia (familial) <b>Congestive heart failure</b> (page 134) <b>Diabetes</b> (page 152) <b>Gingivitis (periodontal disease)</b> (page 203) <b>Halitosis</b> (page 209) (if gum disease) <b>Migraine headaches</b> (page 316) <b>Parkinson's disease</b> (page 345) Renal (kidney) failure
★☆☆	<b>Alzheimer's disease</b> (page 19) <b>Athletic performance</b> (page 43) <b>Breast cancer</b> (page 65) <b>Chronic obstructive pulmonary disease</b> (page 114) (COPD) <b>HIV support</b> (page 239) <b>Infertility (male)</b> (page 305) <b>Insulin resistance syndrome</b> (page 273) (Syndrome X) <b>Lung cancer</b> (page 303) Muscular dystrophy <b>Prostate cancer</b> (page 371)

#### Who is likely to be deficient?

Deficiency is poorly understood, but it may be caused by synthesis problems in the body rather than an insufficiency in the diet. Low blood levels have been reported in people with **heart failure** (page 134), **cardiomyopathy** (page 95), **gingivitis** (page 203) (inflammation of the gums), morbid **obesity** (page 446), **hypertension** (page 246), muscular dystrophy, **diabetes** (page 152), **AIDS** (page 239), and in some people on **kidney** (page 284) dialysis. People with **phenylketonuria** (page 354) (PKU) may be deficient in CoQ<sub>10</sub> because of dietary restrictions.<sup>29</sup> CoQ<sub>10</sub> levels are also generally lower in older people. The test used to assess CoQ<sub>10</sub> status is not routinely available from medical laboratories.

#### Which form of coenzyme Q<sub>10</sub> is best?

Some,<sup>30</sup> but not all,<sup>31</sup> research suggests that a fat-soluble form of CoQ<sub>10</sub> is absorbed better than CoQ<sub>10</sub> in granular (powder) form.<sup>32</sup>

#### How much is usually taken?

Adult levels of supplementation are usually 30–90 mg per day, although people with specific health conditions may supplement with higher levels (with the involvement of a physician). Most of the research on heart conditions has used 90–150 mg of CoQ<sub>10</sub> per day. People with **cancer** (page 87) who consider taking much higher amounts should discuss this issue with a doctor before supplementing. There are several anecdotal reports of large amounts of CoQ<sub>10</sub> resulting in improvements in certain types of cancer. However, controlled trials are needed to confirm these preliminary observations. Most doctors recommend that CoQ<sub>10</sub> be taken with meals to improve absorption.

#### Are there any side effects or interactions?

**Congestive heart failure** (page 134) patients who are taking CoQ<sub>10</sub> should not discontinue taking CoQ<sub>10</sub> supplements unless under the supervision of a doctor.

An isolated test tube study reported that the **anticancer** (page 87) effect of a certain cholesterol-lowering drug was blocked by addition of CoQ<sub>10</sub>.<sup>33</sup> So far, experts in the field have put little stock in this report because its results have not yet been confirmed in animal, human, or even other test tube studies. The drug used in the test tube is not used to treat cancer, and preliminary information regarding the use of high amounts of CoQ<sub>10</sub> in humans suggests the possibility of *anticancer activity*.<sup>34, 35, 36</sup>

## COLLOIDAL SILVER

### What is it?

Colloidal silver is a suspension of the element silver in a solution usually water.

Silver, like mercury, was used as a medicine in the late 1800s and early 1900s. Its prime application was as a topical antiseptic. Use of silver, in the form of silver nitrate solution, is still required by law in most states to be used in newborns as a topical eye drop to prevent eye infections (page 265).

In the early 1990s colloidal silver began appearing in the marketplace as a “nutritional supplement.” Although tremendous claims and testimonials have been made for colloidal silver, almost none of these are documented with scientific research. Silver is an effective antimicrobial agent; however, the effective concentrations required for any sort of systemic effect with colloidal silver are not likely to be obtained safely with oral administration.<sup>1</sup> Yet, colloidal silver is promoted by certain distributors as an alternative to antibiotics and as treatment for almost every infectious disease.

In response to the growing popularity and unsubstantiated claims, the U.S. Food and Drug Administration (FDA) issued a Final Rule on August 17, 1999, stating that all over-the-counter (OTC) products containing colloidal silver or silver salts are not recognized as safe nor effective.<sup>2</sup> Colloidal silver products are classified by the FDA as misbranded because adequate directions cannot be written so the general public can use these drugs safely for their intended purposes. The products are also misbranded when their labeling falsely suggests there is substantial scientific evidence to establish the drugs are safe and effective for their intended uses. According to the Final Rule, a colloidal silver product for any drug use will first have to be approved by the FDA under drug application procedures.

Despite this Final Ruling from the FDA, colloidal silver will likely continue to be sold as a trace mineral supplement (page 559) without medical claims or claims of specific benefits, even though its need in human nutrition is unsubstantiated.

### Where is it found?

Colloidal silver is sold as a water-based solution.

**Colloidal Silver has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Minor burns</b> (page 85) (topical antiseptic)

### Who is likely to be deficient?

Silver is not an essential nutrient, and thus no deficiency state exists.

### How much is usually taken?

The typical recommendation is 1 teaspoon per day, with each teaspoon (5 ml) containing 10 parts per million (ppm) of silver or 50 mcg of silver. This amount is in keeping with the average amount of silver consumed from food and water: roughly 350 mcg per day for most people. However, little is known about the relative absorption and toxicity of colloidal silver, compared with that of the silver naturally present in our diet. Because of the lack of long-term safety or efficacy data for colloidal silver, its use cannot be recommended.

### Are there any side effects or interactions?

When taken in low amounts (e.g., 50 mcg daily), the body appears able to efficiently excrete silver. However, any silver the body is unable to excrete accumulates in body tissues and can result in argyria—the depositing of silver in the internal organs, tissues, and skin.<sup>3</sup> Argyria causes the skin to turn gray or bluish gray and to turn dark on exposure to strong sunlight. This discoloration is permanent and there is no known effective treatment for it. In addition to argyria, the intake of very large amounts (far in excess of the amount that causes discoloration of the skin) of silver can cause neurological and organ damage and **atherosclerosis** (page 38).

The estimated amount of silver accumulation over a one-year period that is required to produce argyria is 1 to 6 grams. This amount is very large compared to the 50 mcg typically recommended and consumed by people using OTC colloidal silver products. Using the most conservative figure, 1,000 mg (1 gram) of silver corresponds to the silver content in 100 liters of 10 ppm colloidal silver, 50 liters of 20 PPM colloidal silver, or 33.3 liters of 30 PPM colloidal silver.

## CONJUGATED LINOLEIC ACID

### What is it?

Conjugated linoleic acid (CLA) is a slightly altered form of the essential fatty acid linoleic acid.

Preliminary animal and test tube research suggests that CLA might reduce the risk of **cancers** (page 87) at several sites, including **breast** (page 65), **prostate** (page 371), colorectal, **lung** (page 298), skin, and stomach.<sup>1, 2, 3, 4</sup> Whether CLA will have a similar protective effect for people has yet to be demonstrated in human research.

In a double-blind study, volunteers participating in an exercise program received 600 mg of CLA or a placebo three times per day for 12 weeks. Compared with placebo, CLA significantly reduced percent body fat, but did not significantly reduce body weight.<sup>5</sup> In a double-blind study of obese men, supplementation with 4.2 grams of CLA per day for four weeks produced a small but statistically significant reduction in waist size. However, compared with the placebo, CLA did not promote weight loss.<sup>6</sup> At present, there is not sufficient evidence to support the use of CLA as a treatment for obesity.

Animal research suggests an effect of CLA supplementation on reducing **body fat** (page 446).<sup>7, 8</sup> Limited controlled human research found 5.6-7.2 grams per day of CLA produced nonsignificant gains in muscle size and strength in experienced<sup>9</sup> and inexperienced<sup>10</sup> weight-training men.

Animal research also suggests an effect of CLA supplementation on limiting **food allergy** (page 14) reactions,<sup>11</sup> preventing **atherosclerosis** (page 38),<sup>12, 13</sup> and improving glucose tolerance.<sup>14</sup> As with the cancer research, the effects of CLA on these conditions in humans remains unclear.

### Where is it found?

CLA is found mainly in dairy products and also in beef and poultry, eggs, and corn oil. Bacteria that live in the intestine of humans can produce CLA from linoleic acid, but supplementation of a rich source of linoleic acid did not produce increases in blood levels of CLA in one human study.<sup>15</sup> CLA is available as a supplement.

**CLA has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Athletic performance</b> (page 43) (body composition and strength)

### Who is likely to be deficient?

No deficiencies of CLA are reported or believed to occur, since it is not an essential nutrient.

### How much is usually taken?

Animal research uses very large amounts, equivalent to several grams per day for humans. Until human research is conducted with CLA, the appropriate amount to take of this nutrient remains unclear.

### Are there any side effects or interactions?

**Overweight** (page 446) volunteers who took 4.5 grams of CLA per day for one year had an increase in their blood levels of lipoprotein(a), a risk factor for heart disease.<sup>16</sup> While the significance of this change is not certain, it is possible that long-term use of CLA could increase the risk of developing **heart disease** (page 98).

In a double-blind study of people with **type 2 diabetes** (page 152), supplementing with 3 grams of CLA per day for eight weeks significantly increased blood glucose levels by 6.3% and decreased insulin sensitivity.<sup>17</sup> A reduction in insulin sensitivity was also seen in a study of overweight men without diabetes after treatment with 3 grams of CLA per day for three months,<sup>18</sup> although in a study of young sedentary men, 4 grams of CLA per day for eight weeks improved insulin sensitivity.<sup>19</sup> Thus, although the studies are conflicting, CLA may be harmful for some people who have, or are at risk of developing, diabetes. One unpublished human trial reported isolated cases of gastrointestinal upset.<sup>20</sup>

## COPPER

### What is it?

Copper is an essential trace element present in the diet and in the human body. It is needed to absorb and uti-

lize **iron** (page 540). It is also part of the **antioxidant** (page 467) **enzyme** (page 506), superoxide dismutase (SOD). Copper is needed to make adenosine triphosphate (ATP), the energy the body runs on. Synthesis of some hormones requires copper, as does the synthesis of collagen (the “glue” that holds connective tissue together). In addition, the enzyme, tyrosinase, which plays a role in the production of skin pigment, requires copper to function.

Copper supplementation has been shown to increase SOD levels in humans.<sup>1</sup>

### Where is it found?

The best source of copper is oysters. Nuts, dried legumes, cereals, potatoes, vegetables, and meat also contain copper.

### Copper has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Anemia</b> (page 25)
★★☆	<b>High cholesterol</b> (page 223) <b>Menkes' disease</b> (page 311) (injectable copper histidine) <b>Osteoporosis</b> (page 333) <b>Wound healing</b> (page 319)
★☆☆	<b>Athletic performance</b> (page 43) <b>Benign prostatic hyperplasia</b> (page 58) <b>Cardiac arrhythmia</b> (page 93) <b>Hypoglycemia</b> (page 251) <b>Peripheral vascular disease</b> (page 352) <b>Rheumatoid arthritis</b> (page 387) <b>Sprains and strains</b> (page 412)

### Who is likely to be deficient?

Many people consume slightly less than the “safe and adequate range” of copper, 1.5–3.0 mg per day. Little is known about the clinical effects of these marginally adequate intakes, though frank copper deficiency is uncommon. Children with **Menkes' disease** (page 311) are unable to absorb copper normally and become severely deficient unless medically treated early in life. Deficiency can also occur in people who supplement with zinc without also increasing copper intake. **Zinc** (page 614) interferes with copper absorption.<sup>2</sup> Health consequences of zinc-induced copper deficiency can be quite serious.<sup>3</sup> In the absence of copper supplementation, **vitamin C** (page 604) supplementation has also

been reported to mildly impair copper metabolism.<sup>4</sup> Copper deficiency can result in anemia, lower levels of HDL (“good”) **cholesterol** (page 223), or **cardiac arrhythmias** (page 93).

### How much is usually taken?

Most people consume less than the recommended amount of this mineral. Some doctors recommend supplementing the average diet with 1–3 mg of copper per day. While the necessity of supplementing a normal diet with copper has not been proven, most people who take **zinc** (page 614) supplements, including the zinc found in **multivitamin-mineral supplements** (page 559), should probably take additional copper.

Cupric oxide (CuO) is a form of copper frequently used in vitamin-mineral supplements sold over-the-counter. However, animal studies have shown conclusively this form of copper is poorly absorbed from the gut; it should therefore not be used in supplements.<sup>5, 6, 7, 8</sup> Several other forms of copper (including copper sulfate, cupric acetate, and alkaline copper carbonate) are better absorbed, and are therefore preferable to cupric oxide.<sup>9</sup>

### Are there any side effects or interactions?

The level at which copper causes problems is unclear. But in combination with **zinc** (page 614), up to 3 mg per day is considered safe. People drinking tap water from new copper pipes should consult their doctor before supplementing, since they might be getting enough (or even too much) copper from their water. People with **Wilson's disease** (page 453) should never take copper.

Zinc interferes with copper absorption. People taking zinc supplements for more than a few weeks should also take copper (unless they have Wilson's disease). In the absence of copper supplementation, **vitamin C** (page 604) may interfere with copper metabolism. Copper improves absorption and utilization of **iron** (page 540).

Preliminary evidence shows that the levels of copper in the blood were higher among people who died from coronary **heart disease** (page 98) than among those who did not.<sup>10</sup> However, animal studies and some human studies suggest that, if anything, copper may prevent the development of heart disease. Although it is not clear why people who died of heart disease had elevated copper levels, this finding could be due to chronic inflammation, which is known to be associated with increased copper levels.<sup>11</sup>

## CREATINE MONOHYDRATE

### What is it?

Creatine (creatine monohydrate) is a colorless, crystalline substance used in muscle tissue for the production of phosphocreatine, an important factor in the formation of adenosine triphosphate (ATP), the source of energy for muscle contraction and many other functions in the body.<sup>1, 2</sup>

Creatine monohydrate supplementation increases phosphocreatine levels in muscle in most people, especially when accompanied by exercise or carbohydrate intake.<sup>3, 4</sup> However, about 30% of people who take creatine supplements fail to retain significant quantities in the muscle,<sup>5, 6</sup> which may explain the inconsistent results reported in studies of the effects of creatine on **athletic performance** (page 43).

Creatine may increase exercise-related gains in lean body mass,<sup>7, 8, 9</sup> though how much of these gains represents more muscle and how much is simply water retention is unclear.<sup>10</sup> Most, though not all, controlled studies have shown that 20 grams per day of creatine monohydrate taken for five to six days by sedentary or moderately active people, improves performance and delays muscle fatigue during short-duration, high-intensity exercise such as sprinting or weight lifting.<sup>11, 12, 13</sup> However, elderly people appear to gain only minimal, if any, exercise performance benefits from creatine supplementation,<sup>14, 15</sup> and performance outcomes for trained athletes using creatine supplements in competitive situations have not been consistent.<sup>16, 17, 18</sup> Creatine supplementation does not appear to increase endurance performance and may impair it by contributing to weight gain.<sup>19</sup>

Very little research has been done to investigate the exercise performance effects of long-term (over one month) creatine supplementation. Two controlled long-term trials using untrained women<sup>20</sup> or trained men<sup>21</sup> found that creatine improved gains made in strength and lean body mass from weight-training programs. However, a third preliminary trial found only insignificant gains from creatine supplementation in weight-training football players.<sup>22</sup>

The amount of creatine within cells may be deficient in people with muscular dystrophy. This deficiency may contribute to the weakness and degeneration of muscle tissue seen in this condition. A case report described a 9-year old boy with muscular dystrophy who experienced improved muscle performance after crea-

tine supplementation.<sup>23</sup> A double-blind trial found that creatine supplementation (10 grams per day for adults, 5 grams per day for children) slightly but significantly improved muscle strength and performance of daily activities in people with varying types of muscular dystrophy.<sup>24</sup> Creatine supplementation has also been reported to improve strength in certain rare diseases of muscle and energy metabolism.<sup>25, 26, 27</sup>

For people with **congestive heart failure** (page 134), intravenous creatine has been found to improve heart function, but oral supplementation has not been effective, though skeletal muscle function does improve.<sup>28, 29</sup>

A double-blind, study found that 20 grams per day of creatine taken for five days followed by 10 grams per day for 51 days significantly lowered serum total **cholesterol** (page 223) and **triglycerides** (page 235), but did not change either LDL or HDL cholesterol, in both men and women.<sup>30</sup> However, another double-blind trial found no change in any of these blood levels in trained athletes using creatine during a 12-week strength training program.<sup>31</sup> Creatine supplementation in this negative trial was lower—only 5 grams per day was taken for the last 11 weeks of the study.

### Where is it found?

Creatine is produced naturally in the human liver, pancreas, and kidneys. It is concentrated primarily in muscle tissues, including the heart. Animal proteins, including fish, are the main source of the 1–2 grams per day of dietary creatine most people consume. Supplements in the form of creatine monohydrate are well absorbed and tolerated by the stomach.

### Creatine monohydrate has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Athletic performance</b> (page 43) (for high-intensity, short duration exercise or sports with alternating low- and high-intensity efforts)
★★☆	<b>Athletic performance</b> (page 43) (for non-weight bearing endurance exercise)
★☆☆	<b>Congestive heart failure</b> (page 134) <b>High cholesterol</b> (page 223) <b>High triglycerides</b> (page 235) Muscular dystrophy

### Who is likely to be deficient?

People involved in intense physical activity, especially those limiting their intake of red meat, may have low muscle stores of creatine. Several muscle diseases, as well as **rheumatoid arthritis** (page 387), and chronic circulatory and respiratory diseases, are associated with lowered creatine levels.<sup>32</sup>

### How much is usually taken?

Two methods are used for supplementing with creatine. In the loading method, 20 grams of creatine per day (in four divided amounts mixed well in warm liquid) are taken for five to six days.<sup>33</sup> Muscle creatine levels increase rapidly, which is beneficial if a short-term rise in force is needed, such as during a weight-lifting competition, football game, or sprinting. To maintain muscle creatine levels after this loading period, 2–10 grams per day may be effective.<sup>34, 35</sup>

In another method, 3 grams of creatine monohydrate per day are taken over an extended **training** (page 43) period of at least four weeks, during which muscle creatine levels rise more slowly, eventually reaching levels similar to those achieved with the loading method.<sup>36</sup> However, no trials testing exercise performance changes have been done using this method. Taking creatine with sugar appears to maximize muscle uptake.<sup>37, 38</sup>

Caffeine intake should not be excessive, as large amounts may counteract the benefits of creatine supplementation.<sup>39</sup>

### Are there any side effects or interactions?

Little is known about long-term side effects of creatine, but no consistent toxicity has been reported in studies of creatine supplementation. In a study of side effects of creatine, **diarrhea** (page 163) was the most commonly reported adverse effect of creatine supplementation, followed by muscle cramping.<sup>40</sup> Some reports showed that kidney, liver, and blood functions were not affected by short-term higher amounts<sup>41, 42</sup> or long-term lower amounts<sup>43, 44</sup> of creatine supplementation in healthy young adults. In a small study of people taking 5–30 grams per day, no change in kidney function appeared after up to five years of supplementation.<sup>45</sup> However, interstitial nephritis, a serious kidney condition, developed in an otherwise healthy young man, supplementing with 20 grams of creatine per day.<sup>46</sup> Improvement in kidney function followed avoidance of creatine. Details of this case strongly suggest that creatine supplementation triggered this case of kidney disease. Creatine supplementation may also be dangerous for

people with existing kidney disease. In one report, a patient with nephrotic syndrome (a kidney disorder) developed glomerulosclerosis (another serious kidney condition) while taking creatine. When the creatine was discontinued, the glomerulosclerosis resolved.<sup>47</sup>

Muscle cramping after creatine supplementation has been anecdotally reported in three studies.<sup>48, 49, 50</sup>

## CYSTEINE

### What is it?

Cysteine is a nonessential **amino acid** (page 465) (protein building block), meaning that cysteine can be made in the human body. Cysteine is one of the few amino acids that contains **sulfur** (page 590). This allows cysteine to bond in a special way and maintain the structure of proteins in the body. Cysteine is a component of the **antioxidant** (page 467) **glutathione** (page 531). The body also uses cysteine to produce **taurine** (page 590), another amino acid.

Cysteine can also be converted into glucose and used as a source of energy. Cysteine strengthens the protective lining of the stomach and intestines, which may help prevent damage caused by aspirin and similar drugs.<sup>1</sup> In addition, cysteine may play an important role in the communication between **immune system** (page 255) cells.<sup>2</sup> Cysteine is rarely used as a dietary supplement. **N-acetyl cysteine** (page 562) (NAC), which contains cysteine, is more commonly used as a supplement.

### Where is it found?

The body can synthesize cysteine from **methionine** (page 557) and other building blocks. Cysteine, the **amino acid** (page 465) from which NAC is derived, is found in most high-protein foods.

### Who is likely to be deficient?

According to several studies, blood levels of cysteine and **glutathione** (page 531) are low in people infected with **HIV** (page 239).<sup>3, 4, 5</sup> Cysteine has a role in the proper function of the **immune system** (page 255), so a deficiency of this **amino acid** (page 465) may either contribute to, or result from, immune suppression associated with HIV.

### How much is usually taken?

Most people do not need to supplement with cysteine. Almost nothing is known about appropriate supple-

mental levels, in part because almost all clinical research has been done with **N-acetyl cysteine** (page 562) and not cysteine itself.

#### **Are there any side effects or interactions?**

No consistent adverse effects of **NAC** (page 562) have been reported in humans. One small study found that daily amounts of 1.2 grams or more could lead to oxidative damage.<sup>6</sup> Extremely large amounts of cysteine, the **amino acid** (page 465) NAC is derived from, may be toxic to nerve cells in rats.<sup>7</sup>

Adequate amounts of **methionine** (page 557) are needed in the diet, as the precursor to cysteine, to prevent cysteine deficiency.

## D-MANNOSE

#### **What is it?**

D-mannose is a simple sugar structurally related to glucose. It is absorbed slowly from the gastrointestinal tract, and then a large proportion of it is excreted into the urine.<sup>1</sup>

#### **Where is it found?**

D-Mannose is in many fruits, including Peaches, apples, oranges, cranberries, and blueberries.

**D-Mannose has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Urinary tract infections</b> (page 436)

#### **Who is likely to be deficient?**

As D-mannose is not an essential nutrient, except in certain rare genetic disorders people produce sufficient amounts to provide for the bodies' needs.

#### **How much is usually taken**

Some doctors report that D-mannose might help prevent or treat urinary tract infections caused by *E. coli* and recommend 1 teaspoon (5 ml) dissolved in water or juice every two to three hours while awake.<sup>2</sup>

#### **Are there any side effects or interactions?**

Test tube studies suggest that consuming large amounts of mannose might lead to birth defects,<sup>3</sup> although this is

not considered a likely risk in humans consuming mannose from foods and naturally producing their own mannose.<sup>4</sup> Nonetheless, until more is known, pregnant women should use supplemental mannose with caution.

## DHEA

#### **What is it?**

DHEA (dehydroepiandrosterone) is one of the hormones produced by the adrenal glands. After being secreted by the adrenal glands, it circulates in the bloodstream as DHEA-sulfate (DHEAS) and is converted as needed into other hormones.

Little is known about how DHEA works in the body.<sup>1</sup> Confusing the picture is the fact that DHEA often has different effects in men, premenopausal women, and postmenopausal women.<sup>2</sup> Supplementation with DHEA-S (a form of DHEA) has resulted in increased levels of testosterone and androstenedione, two steroid hormones.<sup>3</sup>

The conversion of DHEA into testosterone<sup>4</sup> may account for the fact that low blood levels of DHEA have been reported in some men with **erectile dysfunction** (page 185). The findings of a double-blind trial using 50 mg supplements of DHEA taken daily for six months suggests that DHEA may improve erectile function in some men.<sup>5</sup>

Some,<sup>6,7</sup> but not all,<sup>8,9</sup> clinical trials have found that DHEA supplementation lowers fat mass without reducing total **body weight** (page 446).<sup>10</sup> In one trial, the reduction in fat mass occurred in men but not in women.<sup>11</sup>

DHEA is believed to indirectly affect blood sugar levels, but information remains incomplete and contradictory. Attempts to affect blood sugar levels in humans have led to improvements,<sup>12</sup> no effect,<sup>13</sup> and, at very high amounts (1,600 mg DHEA per day), a worsening of tolerance to sugar.<sup>14</sup>

DHEA modulates **immunity** (page 255). A group of elderly men with low DHEA levels who were given 50 mg of DHEA per day for 20 weeks experienced a significant activation of immune function.<sup>15</sup> Postmenopausal women have also shown increased immune functioning in just three weeks when given DHEA in double-blind research.<sup>16</sup>

Some reports have suggested that DHEA might reduce the risk of **heart disease** (page 98), perhaps by lowering **cholesterol levels** (page 223). DHEA may

also be a blood thinner, an effect that in theory should help protect against heart disease.<sup>17</sup> However, most research supports the idea that DHEA protects against heart disease only weakly for men, and not at all for women.<sup>18, 19</sup> In fact, higher levels of DHEA and DHEAS have been associated with cardiovascular risk factors in women, including **high blood pressure** (page 246) and smoking.<sup>20</sup> Moreover, DHEA has also been reported to lower HDL ("good" cholesterol).<sup>21</sup> Until more is known, DHEA should not be used to protect against heart disease.

Claims have appeared that DHEA is an anti-aging hormone. However, the fact that young people have higher levels of DHEA than older people does not necessarily mean that supplementing DHEA will make people appear younger. In some,<sup>22</sup> but not all,<sup>23</sup> double-blind trials, DHEA has improved the sense of well being in elderly individuals. In one double-blind trial, DHEA supplementation did appear to reduce some of the adverse effects of aging, though it did not create "supermen/superwomen."<sup>24</sup> In that trial, healthy elderly women and men were given either 50 mg of DHEA or a placebo daily for one year. In addition to a re-establishment of more youthful levels of DHEAS, slight increases were also observed in other hormones, such as testosterone and estrogens. In women over 70 years of age, bone mineral loss was improved. A significant increase in most measures of libido was also seen in these older women. Improvements of the skin were also observed in both women and men, but particularly in women, in terms of hydration, thickness, pigmentation and production of sebum (oily secretion that lubricates the skin and hair).

**Systemic lupus erythematosus** (page 421) (SLE), an autoimmune disease, has been linked to abnormalities in sex hormone metabolism.<sup>25</sup> Supplementation with very large amounts of DHEA (200 mg per day) improved clinical status and reduced the number of exacerbations of SLE in a double-blind trial.<sup>26</sup> A preliminary trial has confirmed the benefit of 50-200 mg per day of DHEA for people with SLE.<sup>27</sup>

DHEA may play some role in protecting against **depression** (page 145). Low DHEA levels have been reported in older women suffering from this condition, though at least one report has linked severe depression to *increased* DHEA levels. After six months using 50 mg DHEA per day, "a remarkable increase in perceived physical and psychological well-being" was reported in both men and women in one double-blind trial.<sup>28</sup> In another double-blind trial, after only six weeks of tak-

ing DHEA at levels up to 90 mg per day, at least a 50% reduction in depression was seen in 5 of 11 participants.<sup>29</sup> Other researchers have reported dramatic reductions in depression at extremely high amounts of DHEA (90-450 mg per day) given for six weeks to adults who first became depressed after age 40 (in men) or at the time of **menopause** (page 311) (in women) in a double-blind trial.<sup>30</sup> Limiting supplementation to only two weeks is inadequate in treating people with depression.<sup>31</sup>

Despite the dramatic results reported in trials lasting at least six weeks, some experts claim that in clinical practice, DHEA appears to be effective for only a minority of depressed people.<sup>32</sup> Moreover, due to fears of potential side effects, most healthcare professionals remain concerned about the use of DHEA. As with other uses of DHEA, depressed people should not take this hormone without supervision from a healthcare professional.

### Where is it found?

DHEA is produced by the adrenal glands. A synthetic form of this hormone is also available as a supplement in tablet, capsule, liquid, and sublingual form. Some products claim to contain "natural" DHEA precursors from **wild yam** (page 759). However, the body cannot convert these substances into DHEA<sup>33</sup> (although a series of reactions in a laboratory can make the conversion).

**Dehydroepiandrosterone (DHEA) has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Addison's Disease (to correct deficiency) <b>Crohn's disease</b> (page 141) <b>Depression</b> (page 145) <b>Erectile dysfunction</b> (page 185) <b>HIV support</b> (page 239) (for fatigue and depression) <b>Lupus</b> (page 421) <b>Schizophrenia</b> (page 393) <b>Ulcerative colitis</b> (page 433)
★★☆	<b>Alzheimer's Disease</b> (page 19) <b>Chronic fatigue syndrome</b> (page 111) <b>Immune Function</b> (page 255) <b>Menopause</b> (page 311) Multi-infarct dementia <b>Osteoporosis</b> (page 333) <b>Weight loss</b> (page 446)

### Who is likely to be deficient?

Meaningful levels of DHEA do not appear in food, and therefore *dietary* deficiency does not exist. Some people, however, may not synthesize enough DHEA. DHEA levels peak in early adulthood and then start a lifelong descent. By the age of 60, DHEA levels are only about 5–15% of what they were at their peak at younger ages.<sup>34</sup> Whether the lower level associated with age represents a deficiency or a normal part of aging that should not be tampered with remains unknown.

People with true adrenal insufficiency (i.e., Addison's Disease; *not* the hypothetical adrenal "fatigue" or "burnout" that is sometimes incorrectly referred to as "insufficiency") have below normal levels of DHEA. When women with adrenal insufficiency were treated with 50 mg of DHEA every morning for three or four months, their DHEA and DHEAS levels returned to normal, with a simultaneous improvement in well-being and sexuality.<sup>35, 36</sup>

Some studies have reported lower DHEA levels in groups of **depressed** (page 145) patients.<sup>37, 38</sup> However, in one trial, severely depressed people were reported to show *increases* in blood levels of DHEA.<sup>39</sup> Despite these contradictory findings, a few clinical trials suggest that at least some people who are depressed may benefit from DHEA supplementation. (See "What does it do?" above for more information about use of DHEA supplements in the treatment of depression.)

People with multi-infarct dementia (deterioration of mental functions resulting from multiple small strokes) may have lower than normal DHEAS levels, according to a preliminary trial.<sup>40</sup> In this trial, intravenous injection of 200 mg per day of DHEAS for four weeks increased DHEAS levels and improved some aspects of mental function and performance of daily activities.

People infected with **HIV** (page 239)<sup>41</sup> and those with insulin-dependent **diabetes** (page 152),<sup>42</sup> congestive heart failure,<sup>43</sup> **multiple sclerosis** (page 323),<sup>44</sup> **asthma** (page 32),<sup>45, 46</sup> **chronic fatigue syndrome** (page 111),<sup>47, 48</sup> **rheumatoid arthritis** (page 387),<sup>49, 50, 51</sup> **osteoporosis** (page 333), and a host of other conditions have been reported to have low levels of DHEA in most,<sup>52</sup> but not all, studies.<sup>53, 54</sup> In most cases, the meaning of this apparent deficiency is not well understood.

Men under 60 years of age with **erectile dysfunction** (page 185) have been found to have lower DHEAS levels than men without the condition.<sup>55</sup> (See "What does it do?" above for more information about use of DHEA supplements in the treatment of men with erectile dysfunction.)

Most,<sup>56, 57, 58, 59</sup> but not all,<sup>60, 61</sup> studies have found that people with **Alzheimer's disease** (page 19) have lower blood DHEAS levels than do people without the condition.

### How much is usually taken?

Most people do not need to supplement DHEA. The question of who should take this hormone remains controversial. Some experts believe that daily intakes of 5–15 mg of DHEA for women and 10–30 mg for men are appropriate amounts for people with deficient blood levels of DHEA or DHEAS.<sup>62</sup> While a few researchers suggest supplementation with as much as 50 mg per day in postmenopausal women,<sup>63</sup> others consider this level excessive.<sup>64</sup> People should consult a doctor to have DHEA levels monitored before and during supplementation. Healthy people with normal blood levels of DHEA or DHEAS should not take this hormone until more is known about its effects. However, some doctors recommend DHEA supplementation for selected people with **depression** (page 145), autoimmune diseases, or other problems, even if their blood levels are normal.

People with **systemic lupus erythematosus** (page 421) (SLE) have been shown to improve after taking 100–200 mg per day of DHEA. Such large amounts should never be taken without medical supervision.

Discrepancies between label claims and actual DHEA content of DHEA supplements have been reported.<sup>65</sup> Regrettably, the authors of this report failed to identify which brands were properly labeled and which were not.

### Are there any side effects or interactions?

Experts have concerns about the use of DHEA, particularly because long-term safety data do not exist.

Side effects at high intakes (50–200 mg per day) appear to be **acne** (page 4) (in over 50% of people), increased facial hair (18%), and increased perspiration (8%). In a preliminary trial, DHEA was also reported to induce less common side effects, including breast tenderness, weight gain, mood alteration, headache, oily skin, and menstrual irregularity in some people.<sup>66</sup> Since this trial was not controlled, some of these less common "side effects" might have occurred even with a placebo. A case of mania has been reported in an older man who took 200–300 mg of DHEA per day for six months.<sup>67</sup> However, in that case report, other causes of mania could not be ruled out.

Significant increases in testosterone levels in both

men and women have been reported in some trials.<sup>68, 69</sup> Other reports have found this change in women but not in men.<sup>70</sup> An increase in testosterone might increase the risk of several **cancers** (page 87), and high amounts of DHEA have caused cancer in animals.<sup>71, 72</sup> Moreover, a possible link between higher DHEA levels and risks of **prostate cancer** (page 371) in humans has been reported.<sup>73</sup> At least one person with prostate cancer has been reported to have had a worsening of his cancer, despite feeling better, while taking very high amounts (up to 700 mg per day) of DHEA.<sup>74</sup>

While younger women with **breast cancer** (page 65) may have low levels of DHEA, postmenopausal women with breast cancer appear to have high levels of DHEA, which has researchers concerned.<sup>75, 76</sup> Most,<sup>77, 78, 79, 80, 81</sup> but not all, studies<sup>82, 83, 84</sup> have found that as DHEA blood levels increase, so does the risk of breast cancer.

Supplementation with high levels of DHEA (100 mg per day) has adversely affected other indicators of cancer risk in both women and men.<sup>85, 86</sup> Elevated DHEA levels have been reported to be associated with both higher,<sup>87</sup> and lower risk for ovarian cancer.<sup>88</sup> The reason for this discrepancy is unknown.

The lack of knowledge about how DHEA supplementation might affect cancer risks provides a reason for caution. Until more is known, people with **breast** (page 65) or **prostate cancer** (page 371) or a family history of these conditions should avoid supplementing with DHEA.

Although *anticancer* effects of DHEA have also been reported,<sup>89</sup> they involve trials using animals that do not process DHEA the way humans do. Therefore, these positive effects may have no relevance for people.

Some doctors recommend that people taking DHEA have liver enzymes measured routinely. Anecdotes of DHEA supplementation (of at least 25 mg per day) leading to **heart arrhythmias** (page 93) have appeared.<sup>90</sup>

The relationship between DHEA, blood pressure, and heart disease is poorly understood. Increased blood levels of DHEAS have been associated with increased blood pressure<sup>91</sup> and other **cardiovascular risk factors** (page 98) in some,<sup>92</sup> but not all,<sup>93</sup> studies. One study found that people with hypertension had significantly *decreased* blood levels of DHEA.<sup>94</sup> Until clinical trials clear up these inconsistencies and confirm its safety, people with **hypertension** (page 246) should avoid using DHEA, except under the close supervision of a doctor.

At only 25 mg per day, DHEA has lowered HDL cholesterol while increasing insulin-like growth factor (IGF).<sup>95</sup> Decreasing HDL could increase the risk of heart disease. Increasing IGF might increase the risk of breast cancer.

### Special United Kingdom considerations

DHEA is either not available or may require a prescription. People should check with their physician.

## DIGESTIVE ENZYMES

**See also:** **Bromelain** (page 481)

### What are they?

Digestive enzymes are complex proteins involved in digestion that stimulate chemical changes in other substances. They work optimally at specific temperature and pH. Digestive enzymes include pancreatic enzymes, plant-derived enzymes, and fungal-derived enzymes. There are three classes of digestive enzymes: proteolytic enzymes needed to digest protein, **lipases** (page 547) needed to digest fat, and amylases needed to digest carbohydrates.

In several conditions that cause **malabsorption** (page 304), such as **pancreatic insufficiency** (page 341) and **cystic fibrosis** (page 143), doctors sometimes prescribe digestive enzymes to improve absorption of food.

Doctors often tell people to try using pancreatic enzymes with meals when they have symptoms of **indigestion** (page 260) that cannot be attributed to a specific cause. In a double-blind study, microencapsulated pancreatic enzymes were shown to reduce **gas, bloating, and fullness** (page 260) after a high-fat meal.<sup>1</sup>

According to one theory, **allergies** (page 14) are triggered by partially undigested protein. Proteolytic enzymes may reduce allergy symptoms by further breaking down undigested protein to sizes that are too small to cause allergic reactions.<sup>2</sup> Limited scientific evidence supports this theory.<sup>3</sup> Proteolytic enzymes such as trypsin, chymotrypsin, and **bromelain** (page 481) are partially absorbed by the body.<sup>4, 5, 6</sup> Once absorbed, they have anti-inflammatory activity and may even demonstrate antitumor effects.<sup>7, 8, 9, 10</sup> In one preliminary study of a handful of pancreatic **cancer** (page 87) patients, the combination of proteolytic enzymes and other cancer treatments appeared to extend survival, despite the fact that most of the patients died.<sup>11</sup>

Proteolytic enzymes may also improve **immune system** (page 255) function, for example, in people with **shingles** (page 401) (herpes zoster), though this area of research has not been adequately explored.<sup>12</sup>

### Where are they found?

Only small amounts of the animal-based proteolytic enzymes, trypsin and chymotrypsin, are found in the diet; however, the pancreas can synthesize these enzymes. The plant-based proteolytic enzyme **bromelain** (page 481) comes from the stems of pineapples and is useful in many conditions. Papain comes from unripe papayas. All of these enzymes are available as supplements.

**Enzymes have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Low back pain</b> (page 293) (chymotrypsin, trypsin) <b>Pancreatic insufficiency</b> (page 341) (including pancreatitis) <b>Sprains and strains</b> (page 412) (chymotrypsin, trypsin)
★★☆	<b>Celiac disease</b> (page 102) <b>Indigestion</b> (page 260) ( <b>Lipase</b> [page 547]) <b>Osteoarthritis</b> (page 328) (bromelain, trypsin, rutosid combination) <b>Tendinitis</b> (page 426) (proteolytic enzymes)
★☆☆	<b>Acne Rosacea</b> (page 4) <b>Chronic candidiasis</b> (page 109) <b>Crohn's disease</b> (page 141) <b>Food allergies</b> (page 14) <b>Gastroesophageal reflux disease</b> (page 198) (GERD) <b>Low back pain</b> (page 293) (papain) <b>Sprains and strains</b> (page 412) (papain)

### Who is likely to be deficient?

People with **pancreatic insufficiency** (page 341) and **cystic fibrosis** (page 143) frequently require supplemental pancreatic enzymes (which include proteolytic enzymes, **lipases** [page 547], and amylases). In addition, those with **celiac disease** (page 102)<sup>13</sup> or **Crohn's disease** (page 141)<sup>14</sup> and perhaps some people suffering from **indigestion** (page 260)<sup>15</sup> may be deficient in pancreatic enzymes. As **bromelain** (page 481) and papain are not essential, deficiencies do not exist.

### How much is usually taken?

The digestive enzymes—proteolytic enzymes, **lipases** (page 547), and amylases—are generally taken together. Pancreatin, which contains all three digestive enzymes, is rated against a standard established by the U.S. Pharmacopeia (USP). For example, “4X pancreatin” is four times stronger than the USP standard. Each “X” contains 25 USP units of amylase, 2 USP units of lipase, and 25 USP units of protease (or proteolytic enzymes). Three to four grams of 4X pancreatin (or a lower amount at higher potency) with each meal is likely to help digest food in some people with pancreatic insufficiency.

Those with chronic pancreatitis need to discuss enzyme intakes with their physician. Under medical supervision, seriously ill people with **pancreatic insufficiency** (page 341) caused by pancreatitis are given very high levels of enzymes to improve fat digestion. In one successful trial, enough pancreatin was used with each meal to supply slightly over 1,000,000 USP units of lipase.<sup>16</sup> Because pancreatin is rapidly emptied from the stomach during digestion, people taking these enzymes may obtain better results by spreading out supplementation throughout the meal.<sup>17</sup>

Supplemental enzymes that state only product weight, but not activity units, may lack potency.

### Are there any side effects or interactions?

The most important digestive enzymes in **malabsorption** (page 304) diseases are usually fat-digesting enzymes called **lipases** (page 547). Proteolytic enzymes can digest, as well as destroy, lipases. Therefore, people with enzyme deficiencies may want to avoid proteolytic enzymes in order to spare lipases.<sup>18</sup> If this is not possible (as most enzyme products contain both), people with malabsorption syndromes should talk with their doctor to see if their condition warrants finding products that contain the most lipase and the least protease.

In theory, too much enzyme activity could be irritating because it could start to “digest” parts of the body as the enzymes travel through the digestive system. Fortunately, that does not happen with supplemental amounts. Research has not determined the level at which such problems might arise.

A serious condition involving damage to the large intestines called fibrosing colonopathy has resulted from the use of pancreatic enzymes in children with **cystic fibrosis** (page 143). In some cases, the problem was linked to the use of high supplemental amounts of enzymes.<sup>19, 20, 21</sup> However, the amount of enzymes used

has not been linked to the problem in all reports.<sup>22</sup> In some cases, lower amounts of enzymes have caused fibrosing colonopathy if the enzymes are enteric-coated.<sup>23</sup> Some researchers now believe that some unknown interaction between the enteric coating and the enzymes themselves may cause damage to the intestines of children with cystic fibrosis.<sup>24</sup> Until more is known, children with cystic fibrosis needing to take pancreatic enzymes should only do so under the careful supervision of a knowledgeable healthcare professional.

## DMAE

### What is it?

DMAE (2-dimethylaminoethanol) is a chemical produced in the brain.

Like choline, DMAE may increase levels of the brain neurotransmitter acetylcholine; however, not all studies confirm that DMAE serves as a precursor to acetylcholine.<sup>1</sup> Early preliminary research suggested that DMAE may relieve the symptoms of **tardive dyskinesia** (page 425) (a trembling disorder caused by long-term anti-psychotic medication),<sup>2</sup> but several controlled studies did not find the effects of DMAE better than placebo.<sup>3</sup> In fact, one case report suggested that DMAE can cause symptoms of tardive dyskinesia.<sup>4</sup>

One small, uncontrolled four-week trial of senile patients given DMAE supplements of 600 mg three times per day, failed to show any changes in memory but did produce positive behavior changes in some of the patients.<sup>5</sup> However, subsequent double-blind research did not find a significant benefit from the use of DMAE in people with Alzheimer's disease.<sup>6</sup>

### Where is it found?

DMAE is found as a supplement, although it is not widely available.

**DMAE has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Alzheimer's disease</b> (page 19) <b>Tardive dyskinesia</b> (page 425)

### Who is likely to be deficient?

No deficiencies of DMAE are reported or believed to occur.

### How much is usually taken?

DMAE supplementation is not recommended at this time.

### Are there any side effects or interactions?

Clinical studies of DMAE have used up to 1,600 mg per day with no reports of side effects.<sup>7</sup> For this reason, DMAE is believed to be relatively nontoxic. However, one study using higher intakes for **Alzheimer's disease** (page 19) patients did report symptoms of drowsiness and confusion with the use of DMAE.<sup>8</sup> A possible side effect of lucid dreaming (in which the dreamer is conscious and in control of a dream) is suggested with DMAE use.<sup>9</sup> **Depression** (page 145) and hypomania (moderate symptoms of mania) have been reported as side effects of DMAE.<sup>10</sup>

## DMSO

### What is it?

DMSO (dimethyl sulfoxide) is a colorless, slightly oily liquid that is primarily used as an industrial solvent.

The use of DMSO for therapeutic applications is controversial, but some evidence indicates that DMSO has anti-inflammatory properties and alleviates **pain** (page 338) when applied to the skin. These effects have been reported particularly with connective tissue diseases (such as scleroderma, **osteoarthritis** [page 328], and **rheumatoid arthritis** [page 387]) and **muscle injuries** (page 412).<sup>1, 2, 3</sup> DMSO applied to the affected area appears to reduce pain by inhibiting transmission of pain messages by nerves and may also soften the abnormal connective tissue associated with disorders such as **Dupuytren's contracture** (page 171), keloids, Peyronie's disease, and scleroderma.<sup>4</sup>

Double-blind and other controlled studies have found a 25% DMSO gel effective for pain relief in osteoarthritis of the knee<sup>5</sup> and a 50% DMSO cream helpful for symptoms of acute reflex sympathetic dystrophy.<sup>6</sup> However, while a double-blind trial successfully used a 10% DMSO gel to reduce pain and improve movement in people with acute **tendinitis** (page 426) of the shoulder or elbow,<sup>7</sup> an older double-blind trial found no difference between the effects of a 70% DMSO solution and a 5% DMSO "placebo" solution.<sup>8</sup>

Preliminary research has suggested that DMSO may help relieve symptoms of amyloidosis of the skin.<sup>9</sup>

Some medical doctors have instilled DMSO into the bladder to treat interstitial cystitis.<sup>10</sup> A study from Malaysia reports that oral DMSO reduced relapse rates for **peptic ulcer** (page 349) significantly better than placebo or the ulcer drug, cimetidine.<sup>11</sup> DMSO is sometimes used by physicians as a vehicle to help absorb other therapeutic agents through the skin.

#### Where is it found?

DMSO is derived from trees as a manufacturing by-product from the processing of paper. Metabolites (breakdown products) of DMSO, such as the sulfide and sulfone forms, are naturally present in the human body. However, the role of these in the body is not clear.

**DMSO has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Tendinitis (page 426) (topical)
★★☆	Osteoarthritis (page 328) (topical) Rheumatoid arthritis (page 387) (topical)
★☆☆	Amyloidosis (topical) <b>Dupuytren's contracture</b> (page 171) (topical) Keloid scars (topical) <b>Peptic ulcer</b> (page 349) Peyronie's disease (topical) Reflex sympathetic dystrophy (topical) Scleroderma (topical) <b>Sprains and strains</b> (page 412) (topical)

#### Who is likely to be deficient?

DMSO is not an essential nutrient and it is not needed in the functions of a healthy body; therefore, deficiencies do not exist.

#### How much is usually taken?

DMSO is not indicated for healthy people. Those who do use this substance should consult a doctor familiar with its use. Some physicians do not recommend the use of DMSO due to concerns about safety and questions about efficacy. The potential for contamination exists in some DMSO products designed for industrial uses. DMSO used topically is rapidly absorbed through intact skin. Therefore, the area of skin (and

the hands applying DMSO) must be clean, because anything on the skin will also be absorbed along with the DMSO.

#### Are there any side effects or interactions?

DMSO frequently causes a **garlic** (page 679)-like body odor and taste in the mouth. Other reported side effects include **stomach upset** (page 260), **sensitivity to light** (page 356), visual disturbances, and headache. Skin irritation can develop at the site where DMSO is applied topically. Only highly purified, properly diluted DMSO should be used and the skin site and applying hand should be thoroughly cleaned before application, because the solvent properties of DMSO allow contaminants to be absorbed through the skin and transported into the bloodstream. Improperly diluted DMSO can also burn the skin. Check with a healthcare professional for appropriate use.

## DOCOSAHEXAENOIC ACID

#### What is it?

Docosahexaenoic acid (DHA), an omega-3 fatty acid, belongs to the class of nutrients called essential fatty acids.

DHA has been shown to reduce levels of blood triglycerides. **High triglycerides** (page 235) are linked with **heart disease** (page 98) in most, but not all, research. DHA alone appears to be just as effective as **fish oils** (page 514) (which contain both DHA and eicosapentaenoic acid [**EPA** (page 514)]) in beneficially lowering triglyceride levels in people at risk for heart disease.<sup>1</sup> In part, this may be because some DHA is converted to EPA in the body.<sup>2</sup> Unlike EPA, however, DHA may not reduce excessive blood clotting.<sup>3</sup>

DHA appears to be essential for normal visual and neurological (nervous system) development in infants.<sup>4, 5</sup> However, DHA supplementation did not affect the development of visual acuity in formula-fed infants in a double-blind trial.<sup>6</sup> Nevertheless, other double-blind research links DHA supplementation in premature infants to better brain functioning.<sup>7</sup> The effects of DHA on the nervous system may well extend beyond infancy. Young adults given 1.5–1.8 grams DHA per day showed less evidence of aggression in response to mental stress, compared with people in the control group in a double-blind trial.<sup>8</sup>

DHA supplementation in healthy young men has been shown to decrease the activity of **immune** (page 255) cells, such as natural killer (NK) cells and the cells that regulate inflammation responses in the body.<sup>9</sup> The anti-inflammatory effects of DHA may be useful in the management of autoimmune disorders; however, such benefits need to be balanced with the potential for increased risk of **infections** (page 265).

DHA deficiency plays an important role in a group of congenital diseases called peroxisomal disorders, which damage the protective covering (myelin) around nerves. Although rare, the worst of these disorders (i.e., Zellweger's syndrome) is life-threatening within the first year of life. Daily oral supplementation of 100–600 mg of DHA has been shown to increase blood levels of DHA, to protect myelin, and to improve the signs and symptoms of these potentially devastating disorders.<sup>10</sup>

### Where is it found?

Cold-water fish, such as mackerel, salmon, herring, sardines, black cod, anchovies, and albacore tuna, are rich sources of DHA and EPA. Similarly, **cod liver oil** (page 514) contains large amounts of DHA and EPA. Certain microalgae contain DHA and are used as a vegetarian source of this nutrient in some supplements. Most **fish oil** (page 514) supplements contain 12% DHA.

### DHA has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Childhood intelligence <b>High blood pressure</b> (page 246) <b>High triglycerides</b> (page 235) Peroxisomal disorders <b>Rheumatoid arthritis</b> (page 387)
★★☆	<b>Depression</b> (page 145) <b>Epilepsy</b> (page 183) (given in combination with EPA) <b>Lupus</b> (page 421) <b>Psoriasis</b> (page 379)
★☆☆	<b>Angina</b> (page 27) <b>Chronic obstructive pulmonary disease</b> (page 114) (COPD) <b>Diabetes</b> (page 152) <b>Dysmenorrhea</b> (page 171) (painful menstruation) <b>Migraine headaches</b> (page 316) <b>Osteoarthritis</b> (page 328)

### Who is likely to be deficient?

Premature infants who are not breast-fed are often DHA-deficient.<sup>11</sup> A link has appeared between DHA deficiency and **Alzheimer's disease** (page 19); however, no evidence at this time indicates that supplementation with DHA will help Alzheimer's patients.<sup>12</sup> Similarly, preliminary evidence shows that children with **attention deficit disorder** (page 55) (ADD) have low DHA levels. However, no evidence demonstrates that DHA supplementation improves ADD.<sup>13</sup> Preliminary evidence suggests that people with a variety of rare but related congenital diseases (Zellweger's syndrome, neonatal adrenoleukodystrophy, and infantile Refsum's disease) may be DHA-deficient, and may even benefit from DHA supplementation.<sup>14</sup> Many doctors believe the diets of most people eating a Western diet do not provide optimal amounts of omega-3 fatty acids.

At least four studies have reported a reduced blood level of omega-3 fatty acids in people with **depression** (page 145).<sup>15, 16, 17, 18</sup>

### How much is usually taken?

Most healthy people do not supplement with **fish oil** (page 514) containing DHA or vegetarian sources of DHA. The level of DHA given to premature infants who are not breast-fed should be determined by a pediatrician. Much of the research in adults has been based on 1–3 grams per day of DHA from fish oil, although higher levels have been taken when isolated DHA from microalgae sources is used.

Because **cod liver oil** (page 514) contains large amounts of **vitamin A** (page 595) and **vitamin D** (page 607), women who are or who could become **pregnant** (page 363) should consult a doctor before taking cod liver oil. Adults should make sure the total amount of vitamin A and vitamin D from cod liver oil and other supplements does not exceed 25,000 IU (7,500 mcg) per day for vitamin A (15,000 IU per day for those over age 65) and 800 IU per day for vitamin D, unless they are being supervised by a doctor.

### Are there any side effects or interactions?

While those with **heart disease** (page 98) and **diabetes** (page 152) often benefit from **fish oil** (page 514) (the primary source of DHA in the diet),<sup>19, 20</sup> such people should check with their doctor before taking more than 3 or 4 grams of fish oil per day for several months. Elevations in blood sugar have sometimes been reported,<sup>21</sup>

though this may simply be due to small increases in **weight** (page 446) resulting from high dietary fish oil.<sup>22</sup> While DHA combined with EPA from fish oil consistently lowers **triglycerides** (page 235), it occasionally increases LDL **cholesterol** (page 223).<sup>23</sup>

Fish oil is easily damaged by oxygen, so small amounts of **vitamin E** (page 609) are often included in fish oil supplements to prevent such oxidative damage.<sup>24</sup> Doctors often recommend that people who supplement with fish oil or DHA take vitamin E supplements to protect EPA and DHA within the body from oxidative damage. Some evidence indicates that vitamin E may be protective against oxidative damage caused by fish oil.<sup>25</sup> However, animal researchers have reported that the oxidative damage caused by DHA alone was not prevented with vitamin E supplementation.<sup>26</sup> The level of oxidative damage caused by DHA has not been shown to result in significant health problems.

Some evidence suggests that adding vitamin E to EPA/DHA may prevent the **fish oil** (page 514)-induced increase in serum glucose.<sup>27</sup> Similarly, the impairment of glucose tolerance sometimes caused by the omega-3 fatty acid has been prevented by the addition of half an hour of moderate exercise three times a week.<sup>28</sup> The effect of DHA by itself on glucose levels has not been adequately studied.

People who take fish oil containing EPA and DHA and who also take 15 grams of pectin per day have been reported to have reductions in LDL **cholesterol** (page 223).<sup>29</sup> This suggests that pectin may overcome the occasional problem of increased LDL cholesterol from fish oil supplementation. The LDL cholesterol-raising effect of EPA and DHA may also be successfully prevented by taking **garlic** (page 679) supplements (or presumably adding garlic to the diet) along with EPA and DHA.<sup>30</sup> Adding pectin or garlic when people supplement with DHA by itself has yet to be studied.

According to a report in a Japanese medical journal, three people at high risk for **colon cancer** (page 123) developed a variety of **cancers** (page 87) after one to two years of supplementation with DHA.<sup>31</sup> To date, this report has not been confirmed by other researchers. To the contrary, test tube studies report that DHA is toxic to cancer cells<sup>32</sup> and may someday be considered as an adjunct to conventional treatment for cancer.<sup>33</sup> Similarly, animal studies suggest that DHA may inhibit cancer.<sup>34</sup>

## EVENING PRIMROSE OIL

### What is it?

Evening primrose oil (EPO), comes from the seeds of the evening primrose plant. Like black currant seed oil and **borage** (page 475) oil, EPO contains gamma linolenic acid (GLA), a fatty acid that the body converts to a hormone-like substance called prostaglandin E<sub>1</sub> (PGE<sub>1</sub>).

PGE<sub>1</sub> has anti-inflammatory properties and may also act as a blood thinner and blood vessel dilator. The anti-inflammatory properties of EPO have been studied in double-blind research with people suffering from **rheumatoid arthritis** (page 387). Some, but not all, studies have reported that EPO supplementation provides significant benefit to these people.<sup>1</sup>

GLA, the primary active ingredient in EPO, has anticancer activity in test tube studies<sup>2</sup> and in some,<sup>3</sup> but not all,<sup>4</sup> animal studies. Injecting GLA into tumors has caused regression of cancer in people in preliminary research.<sup>5</sup> Preliminary evidence in people with cancer suggested "marked subjective improvement,"<sup>6</sup> though not all studies find GLA helpful.<sup>7</sup>

EPO has been reported to lower **cholesterol levels** (page 223) in people in some,<sup>8</sup> but not all,<sup>9</sup> research.

EPO supplementation has been shown to improve skin itching, redness, and dryness associated with kidney dialysis.<sup>10, 11</sup>

Linoleic acid, a common fatty acid found in nuts and seeds and most vegetable oils (including EPO), should theoretically be converted to PGE<sub>1</sub>; but many things can interfere with this conversion, including disease; the aging process; saturated fat; hydrogenated oils; blood sugar problems; and inadequate **vitamin C** (page 604), **magnesium** (page 551), **zinc** (page 614), and **B vitamins** (page 603). Supplements that provide GLA circumvent these conversion problems, leading to more predictable formation of PGE<sub>1</sub>.<sup>12</sup>

### Where is it found?

EPO is found primarily in supplements. Its presumed active ingredient, GLA, can also be found in black currant seed oil and **borage** (page 475) oil supplements. However, it is not known whether the effects of these three oils in the body are the same.

**Evening primrose oil has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Diabetes</b> (page 152)
★★☆	<b>Eczema</b> (page 177) <b>Fibrocystic breast disease</b> (page 189) <b>Osteoporosis</b> (page 333) (in combination with <b>fish oil</b> [page 514]) <b>Premenstrual syndrome (PMS)</b> (page 368) <b>Rheumatoid arthritis</b> (page 387) <b>Skin ulcers</b> (page 409)
★☆☆	<b>Alcohol withdrawal</b> (page 12) <b>Atherosclerosis</b> (page 38) <b>Attention deficit disorder</b> (page 55) <b>Intermittent claudication</b> (page 276) <b>Irritable bowel syndrome</b> (page 280) (IBS) <b>Multiple sclerosis</b> (page 323) <b>Raynaud's disease</b> (page 382) Scleroderma Sjogren's syndrome <b>Tardive dyskinesia</b> (page 425)

### Who is likely to be deficient?

Those with **premenstrual syndrome** (page 368),<sup>13</sup> **diabetes** (page 152),<sup>14</sup> scleroderma,<sup>15</sup> Sjogren's syndrome,<sup>16</sup> **tardive dyskinesia** (page 425),<sup>17</sup> **eczema** (page 177),<sup>18</sup> and other skin conditions<sup>19</sup> can have a metabolic block that interferes with the body's ability to make GLA. In preliminary research, supplementation with EPO has helped people with these conditions.<sup>20, 21, 22, 23, 24</sup>

There is evidence that alcoholics may be deficient in GLA, and a double-blind study suggested that **alcohol withdrawal** (page 12) may be facilitated with EPO supplementation.<sup>25</sup> Many people in Western societies may be at least partially GLA-deficient as a result of aging, glucose intolerance, high dietary fat intake, and other problems. People with deficiencies would presumably benefit from supplemental GLA intake from EPO, black currant seed oil, or **borage** (page 475) oil.

### How much is usually taken?

Although many people may have inadequate levels of GLA, the optimal intake for this nutrient remains unknown. Researchers often use 3,000–6,000 mg of EPO per day, which provides approximately 270–540 mg of GLA.

### Are there any side effects or interactions?

EPO has been reported to exacerbate symptoms of temporal lobe **epilepsy** (page 183), which can sometimes be mistaken for **schizophrenia** (page 393).<sup>26, 27</sup>

Other nutrients are needed by the body, along with EPO, to make PGE<sub>1</sub>. Consequently, some experts suggest that **magnesium** (page 551), **zinc** (page 614), **vitamin C** (page 604), **niacin** (page 598), and **vitamin B<sub>6</sub>** (page 600) should be taken along with EPO.

## FIBER

### What is it?

Dietary fiber comes from the thick cell wall of plants. It is an indigestible complex carbohydrate. Fiber is divided into two general categories—water soluble and water insoluble.

Soluble fiber lowers **cholesterol** (page 223).<sup>1</sup> An analysis of many trials of soluble fiber reveals it has a cholesterol-lowering effect, but the degree of cholesterol reduction in many studies was quite modest.<sup>2</sup> For unknown reasons, diets higher in *insoluble* fiber (mostly unrelated to cholesterol levels) have been reported to correlate better with protection against **heart disease** (page 98) in both men and women.<sup>3, 4</sup>

Soluble fibers can also lower blood sugar levels in people with **diabetes** (page 152), and some researchers find that increasing fiber decreases the body's need for insulin—a good sign for diabetics.<sup>5</sup> However, a research review reveals that just how much moderate amounts of soluble fiber really help people with diabetes remains unclear.<sup>6</sup> As with **heart disease** (page 98), a clear mechanism to explain how *insoluble* fiber helps diabetics has not been identified. Nonetheless, diets high in insoluble fiber (from whole grains) associate with protection from adult-onset diabetes.<sup>7</sup>

Insoluble fiber softens stool, which helps move it through the intestinal tract in less time. For this reason, insoluble fiber is partially effective as a treatment for **constipation** (page 137).<sup>8</sup> The reduction in “transit time” has also been thought to partially explain the link between a high fiber diet and a reduced risk of **colon cancer** (page 123) as found in some studies,<sup>9</sup> though **anticancer** (page 87) effects unrelated to “transit time” have also been reported.<sup>10</sup>

The true relationship between fiber and colon cancer risk has recently been clouded by data coming from

several directions. In animal research, wheat bran is proving to be more protective than other diets containing equal amounts of insoluble fiber, suggesting that fiber in wheat may not be the primary cause of protection sometimes associated with wheat.<sup>11</sup> In human research, a recent well respected study found no significant link between fiber and colon cancer prevention.<sup>12</sup> A trial from South Africa found that avoidance of meat and dairy, and not the presence of fiber, appears to be primarily responsible for a low risk of colon cancer.<sup>13</sup> As a result of these negative findings some researchers and doctors have begun to question the idea that insoluble fiber protects against colon cancer, a concept that had arisen from a large body of older research.

Fiber also fills the stomach, reducing appetite. In theory, fiber should therefore reduce eating, leading to **weight loss** (page 446). However, at least some research has found increased fiber to have no effect on body weight despite decreasing appetite.<sup>14</sup>

Lignan, a fiber-like substance, has mild antiestrogenic activity. Probably for this reason, high lignan levels in urine (and therefore dietary intake) have been linked to protection from **breast cancer** (page 65) in humans.<sup>15</sup>

### Where is it found?

Whole grains are particularly high in insoluble fiber. **Oats** (page 716), barley, beans, fruit (but not fruit juice), **psyllium** (page 732), and some vegetables contain significant amounts of both forms of fiber and are the best sources of soluble fiber. The best source of lignan, by far, is **flaxseed** (page 517) (not flaxseed oil, regardless of packaging claims to the contrary).

**Fiber has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Constipation</b> (page 137) <b>Diabetes</b> (page 152) <b>Diverticular disease</b> (page 168) <b>High cholesterol</b> (page 223)
★★☆	<b>Diarrhea</b> (page 163) <b>Hemorrhoids</b> (page 219) <b>High blood pressure</b> (page 246) <b>Weight loss</b> (page 446)

★★☆

**Cirrhosis** (page 290) (combination of beta-glucan, inulin, pectin, and resistant starch)  
**High triglycerides** (page 235)  
**Irritable bowel syndrome** (page 280) (fiber other than wheat)  
**Kidney stones** (page 284)  
**Peptic ulcer** (page 349)  
**Premenstrual syndrome** (page 368)

### Who is likely to be deficient?

Most people who consume a typical Western diet are fiber-deficient. Eating white flour, white rice, and fruit juice (as opposed to whole fruit) all contribute to this problem. Many so-called whole wheat products contain mostly white flour. Read labels and avoid “flour” and “unbleached flour,” both of which are simply white flour. Junk food is also fiber depleted. The diseases listed above are more likely to occur with low-fiber diets.

The benefits of eating whole grains are largely derived from the beneficial constituents present in the outer layers of the grains, which are stripped away in making white flour and white rice. Preliminary research has found that women who ate mostly whole grain fiber had a lower mortality rate than women who ate a comparable amount of refined grains.<sup>16</sup>

### How much is usually taken?

Western diets generally provide approximately 10 grams of fiber per day. So-called “primitive societies” consume 40–60 grams per day. Increasing fiber intake to the amounts found in primitive diets may be desirable.

### Are there any side effects or interactions?

While people can be **allergic** (page 14) to certain high-fiber foods (most commonly wheat), high-fiber diets are more likely to improve health than cause any health problems. Beans, a good source of soluble fiber, also contain special sugars that are often poorly digested, leading to gas. Special **enzyme** (page 506) products are now available in supermarkets to reduce this problem by improving digestion of these sugars.

Fiber reduces the absorption of many minerals. However, high-fiber diets also tend to be high in minerals, so the consumption of a high-fiber diet does not appear to impair mineral status. However, logic suggests that **calcium** (page 483), **magnesium** (page 551) and **multimineral supplements** (page 559) should not be taken at the same time as a fiber supplement.

Bran, an insoluble fiber, reduces the absorption of calcium enough to cause urinary calcium to fall.<sup>17</sup> In one study, supplementation with 10 grams of rice bran twice a day reduced the recurrence rate of **kidney stones** (page 284) by nearly 90% in recurrent stone formers.<sup>18</sup> However, it is not known whether other types of bran would have the same effect. Before supplementing with bran, people should check with a doctor, because some people—even a few with kidney stones—do not absorb enough calcium. For those people, supplementing with bran might deprive them of much-needed calcium.

People with scleroderma (systemic sclerosis) should consult a doctor before taking fiber supplements or eating high-fiber diets. Although a gradual introduction of fiber in the diet may improve bowel symptoms in some cases, there have been several reports of people with scleroderma developing severe **constipation** (page 137) and even bowel obstruction requiring hospitalization after fiber supplementation.<sup>19</sup>

## FISH OIL AND COD LIVER OIL (EPA AND DHA)

### What is it?

Oil from fish contains eicosapentaenoic acid (EPA) and docosahexaenoic acid (**DHA** [page 509]); both are omega-3 fatty acids.

Most fish oil supplements are 18% EPA and 12% DHA, or a total of 30% omega-3. These omega-3 fatty acids, unlike the omega-3 fatty acid found in flaxseed oil and other vegetable oils (such as alpha linolenic acid), keep blood triglycerides in check (**high triglycerides** [page 235] are generally linked with increased risk of **heart disease** [page 98]) and may inhibit the progression of **atherosclerosis** (page 27).<sup>1</sup> EPA and DHA keep blood from clotting too quickly.

EPA and DHA also have anti-inflammatory activity. As a result, fish oil is used to help people with various inflammatory conditions, such as **Crohn's disease** (page 141)<sup>2</sup> and **rheumatoid arthritis** (page 387).<sup>3</sup> The anti-inflammatory effects of EPA and DHA may also account for the findings of some reports that show fish oil supplementation helps some people with **kidney** (page 284) diseases<sup>4, 5, 6</sup> and may help protect against **chronic obstructive pulmonary disease** (page 114).<sup>7</sup>

The omega-3 fatty acids in fish oil help to balance the omega-6 fatty acids, which are found mostly in vegetable oils. When these two groups of fatty acids are out of balance, the body releases chemicals that promote inflammation. People appear to produce more of these inflammatory chemicals when experiencing psychological stress (e.g., academic examinations). With a fatty acid imbalance, inflammatory response to stress appears to be amplified.<sup>8</sup>

Prostaglandins are hormone-like substances produced within the body that regulate dilation of blood vessels, inflammatory response, and other critical processes. Omega-3 fatty acids are needed for prostaglandin formation. Probably as a result of their effect on prostaglandins responsible for blood vessel dilation, a double-blind trial found that omega-3 fatty acids from fish oil helped to treat people with **Raynaud's disease** (page 382).<sup>9</sup>

**Schizophrenia** (page 393) is linked with abnormalities in fatty acid metabolism, and preliminary research suggests that fish oil supplementation may be helpful to people with schizophrenia.<sup>10</sup> However, a double-blind study that used 3 grams per day of eicosapentaenoic acid failed to demonstrate any benefit for patients with chronic schizophrenia.<sup>11</sup>

DHA is essential for vision in infants. Researchers are now studying this relationship to better understand how much DHA is needed.

EPA and DHA also modulate **immune function** (page 255),<sup>12</sup> probably as a result of their effect on prostaglandin production. Perhaps as a result of this effect, fish oil has helped prevent some types of **cancer** (page 87) in animals<sup>13, 14, 15</sup> and humans,<sup>16</sup> although this evidence remains preliminary.

Preliminary evidence also shows that omega-3 fatty acids from fish oil may help regulate the rhythm of the heart. EPA and DHA have been reported to help prevent **cardiac arrhythmias** (page 93).<sup>17</sup>

### Where is it found?

EPA and **DHA** (page 509) are found in mackerel, salmon, herring, sardines, sablefish (black cod), anchovies, albacore tuna, and wild game. Cod liver oil contains large amounts of EPA and DHA. Fish oil supplements typically contain 18% EPA and 12% DHA, though more purified (i.e., higher in EPA and DHA) fish oil supplements are sometimes available. In addition, DHA is available in a supplement that does not contain significant amounts of EPA.

**Fish oil has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Crohn's disease</b> (page 141) (enteric-coated, free-fatty-acid form of fish oil) <b>High blood pressure</b> (page 246) <b>High triglycerides</b> (page 235) <b>Rheumatoid arthritis</b> (page 387)

★☆☆	<b>Angina</b> (page 27) <b>Chronic fatigue syndrome</b> (page 111) <b>Chronic obstructive pulmonary disease</b> (page 114) (COPD) <b>Colon cancer</b> (page 123) (reduces risk) <b>Diabetes</b> (page 152) <b>Dysmenorrhea</b> (page 171) (painful menstruation) <b>Endometriosis</b> (page 182) <b>Glaucoma</b> (page 206) <b>Migraine headaches</b> (page 316) <b>Multiple sclerosis</b> (page 323) <b>Osteoarthritis</b> (page 328) <b>Osteoporosis</b> (page 333) <b>Photosensitivity</b> (page 356) <b>Preeclampsia</b> (page 361)

### Who is likely to be deficient?

So-called "primitive" diets have much higher levels of EPA and **DHA** (page 509) than modern diets. As a result, some researchers and doctors believe that most people who eat a typical western diet are likely to be consuming less-than-optimal amounts of EPA and DHA. To a very limited extent, omega-3 fatty acids from vegetable sources, such as **flaxseed oil** (page 517), can convert to EPA.

At least four studies have reported a reduced blood level of omega-3 fatty acids in people with **depression** (page 145).<sup>18, 19, 20, 21</sup>

People with **rheumatoid arthritis** (page 387) have been found to have decreased levels of omega-3 fatty acids, such as are found in fish oil, in their joint fluid and blood.<sup>22</sup>

### How much is usually taken?

Presumably, healthy people who frequently eat fatty fish (several times per week) have no need to supplement with fish oil. How much EPA and **DHA** (page 509), if any, should be supplemented by healthy people who do *not* eat much fatty fish, remains unclear.

Most researchers studying the effects of EPA and DHA in humans who have a variety of health conditions have given those people at least 3 grams of the total of EPA plus DHA—an amount that may require 10 grams of fish oil, because most fish oil contains only 18% EPA and 12% DHA.

The health benefits for people with **Crohn's disease** (page 141) have been reported with a special, enteric-coated preparation of purified EPA/DHA manufactured from fish oil. This preparation of purified fatty acids has also been reported to not cause the gastrointestinal symptoms that often result from taking regular fish oil supplements, again suggesting unique benefit.<sup>23</sup>

In one trial, the maximum amount of fish oil tolerated by people being treated for cancer-related weight loss was reported to be approximately 21 grams per day.<sup>24</sup> However, in people who do not have **cancer** (page 87), the maximum tolerated amount may be different.

### Are there any side effects or interactions?

While those with **heart disease** (page 98) and **diabetes** (page 152) have often been reported to benefit from supplementation with fish oil,<sup>25, 26</sup> both groups should check with their doctor before taking more than 3 grams of fish oil per day for several months. Elevations

in blood sugar and **cholesterol** (page 223) levels may occur in some people who take fish oil.<sup>27</sup>

The increase in blood sugar appears to be related in part to the amount of fish oil used.<sup>28</sup> Some evidence suggests that adding **vitamin E** (page 609) to fish oil may prevent the fish oil-induced increase in blood sugar levels.<sup>29</sup> In other research, the impairment of sugar metabolism sometimes caused by supplementation with fish oil has been prevented by the addition of half an hour of moderate exercise three times a week.<sup>30</sup>

While supplementation with fish oil consistently lowers **triglycerides** (page 235), the effect of fish oil on LDL ("bad") cholesterol varies, and in some people, fish oil supplementation has been reported to increase LDL levels.<sup>31</sup> People who took fish oil and who also took 15 grams of pectin per day were reported to have reductions in LDL **cholesterol** (page 223).<sup>32</sup> This suggests that pectin may overcome the occasional problem of increased LDL cholesterol reported in people who supplement with fish oil. The LDL-cholesterol raising effect of EPA and **DHA** (page 509) has also been reported to be prevented by taking **garlic** (page 679) supplements (or presumably including garlic in the diet) along with EPA and DHA.<sup>33</sup>

## FLAVONOIDS

### What are they?

Flavonoids are a class of water-soluble plant pigments. Flavonoids are broken down into categories, though the issue of how to divide them is not universally agreed upon. One system breaks flavonoids into isoflavones, anthocyanidins, flavans, flavonols, flavones, and flavanones.<sup>1</sup> Some of the best-known flavonoids, such as genistein in **soy** (page 587), and **quercetin** (page 580) in onions, can be considered subcategories of categories. Although they are all structurally related, their functions are different. Flavonoids also include hesperidin, rutin, citrus flavonoids, and a variety of other supplements.

While they are not considered essential nutrients, some flavonoids support health by strengthening capillaries and other connective tissue, and some function as anti-inflammatory, antihistaminic, and antiviral agents. Quercetin has been reported to block the "sorbitol pathway" that is linked to many problems associated with **diabetes** (page 152). Rutin and several other flavonoids may also protect blood vessels.

As **antioxidants** (page 467), some flavonoids, such

as quercetin, protect LDL ("bad") **cholesterol** (page 223) from oxidative damage. Others, such as the anthocyanidins from **bilberry** (page 634), purple cabbage, and grapes, may help protect the lens of the eye from **cataracts** (page 101). Animal research suggests that naringenin, found in grapefruit, may have **anticancer** (page 87) activity.<sup>2</sup> Soy isoflavones are also currently being studied to see if they help fight cancer.

In a small, preliminary trial, rutoside (500 mg twice daily), a derivative of the flavonoid, rutin, combined with **vitamin C** (page 604) (500 mg twice daily) produced marked improvement in three women with progressive pigmented purpura (PPP), a mild skin condition.<sup>3</sup> Although not a serious medical condition, cosmetic concerns lead persons with PPP to seek treatment with a variety of drugs. The vitamin C/rutoside combination represents a promising, non-toxic alternative to these drug treatments, but larger, controlled trials are needed to confirm these preliminary results.

### Where are they found?

Flavonoids are found in a wide range of foods. For example, flavanones are in citrus, isoflavones in soy products, anthocyanidins in wine and **bilberry** (page 634), and flavans in apples and tea.

**Flavonoids have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Chronic venous insufficiency</b> (page 116) (rutin) <b>Edema</b> (page 180) (water retention) (coumarin, hydroxyethylrutosides) <b>Hepatitis</b> (page 220) (catechin)

- Retinopathy** (page 385) (**quercetin** [page 580], rutin)

### Who is likely to be deficient?

Flavonoid deficiencies have not been reported.

### How much is usually taken?

Flavonoid supplements are not required to prevent deficiencies in people eating a healthy diet. Healthcare practitioners commonly recommend 1,000 mg of citrus flavonoids taken one to three times per day. Alternatively, 240–600 mg of **bilberry** (page 634) (standardized to 25% anthcyanosides) may be taken per day.

### Are there any side effects or interactions?

No consistent side effects have been linked to the flavonoids except for catechin, which can occasionally cause fever, anemia from breakdown of red blood cells, and **hives** (page 245).<sup>4, 5</sup> These side effects subsided when treatment was discontinued.

In 1980, **quercetin** (page 580) was reported to induce cancer in animals.<sup>6</sup> Most further research did not find this to be true, however.<sup>7, 8</sup> While quercetin is mutagenic in test tube studies, it does not appear to be mutagenic in animal studies.<sup>9</sup> In fact, quercetin has been found to inhibit both tumor promoters<sup>10</sup> and human cancer cells.<sup>11</sup> People who eat high levels of flavonoids

have been found to have an overall *lower* risk of getting a wide variety of **cancers** (page 87),<sup>12</sup> though preliminary human research studying only foods high in quercetin has found no relation to cancer risk one way or the other.<sup>13</sup> Despite the confusion, in recent years experts have shifted their view of quercetin from concerns that it might cause cancer in test tube studies to guarded hope that quercetin has anticancer effects in humans.<sup>14</sup>

The flavonoids work in conjunction with **vitamin C** (page 604). Citrus flavonoids, in particular, improve the absorption of vitamin C.<sup>15, 16</sup>

## FLAXSEED AND FLAXSEED OIL

### What is it?

Flaxseed, called linseed in some countries, is a good source of dietary **fiber** (page 512), **omega-3 fatty acids** (page 509), and lignans. Each of these components may contribute to the health effects of eating flaxseed, but flaxseed oil contains no fiber and very little lignan.

Like most vegetable oils, flaxseed oil contains linoleic acid, an essential fatty acid needed for survival. But unlike most oils, it also contains significant amounts of another essential fatty acid, alpha linolenic acid (ALA).

ALA is an omega-3 fatty acid. To a limited extent, the body turns ALA into eicosapentaenoic acid (EPA)—an omega-3 fatty acid found in **fish oil** (page 514)—which in turn converts to beneficial prostaglandins. (Prostaglandins are hormone-like substances made in many parts of the body rather than coming from one organ, as most hormones do.)

While fish oil has been shown to have anti-inflammatory activity, an anti-inflammatory effect of flaxseed oil has not been demonstrated conclusively. Some doctors have argued that, because ALA can be converted to EPA and **DHA** (page 509) (the fatty acids found in **fish oil** [page 514]), flaxseed oil should be useful for the same conditions as fish oil. However, the conversion of ALA to EPA and DHA is limited, so that argument may turn out to be incorrect. For example, while numerous studies have shown that fish oils are beneficial for **rheumatoid arthritis** (page 387), flaxseed oil failed to work for this condition in the only known trial.<sup>1</sup> In 1994, a diet purportedly high in ALA was successful in preventing **heart disease** (page 98),<sup>2</sup> but this study al-

tered many dietary factors, so ALA may not have been solely responsible for the outcome.<sup>3</sup> Flaxseed oil does not appear to be a good replacement for fish oil for people with elevated **triglycerides** (page 235).<sup>4,5</sup> ALA does not reduce excess platelet aggregation ("sticky platelets"), another risk factor for heart disease, the way fish oil does.<sup>6</sup> However, flaxseed oil may help **lower cholesterol** (page 223),<sup>7</sup> and research specific to flaxseed oil indicates that it may also **lower blood pressure** (page 246).<sup>8</sup>

Flaxseed is the most abundant food source of lignans, a family of phytochemicals that is drawing the interest of many health researchers.<sup>9,10,11</sup> Lignans are not actually present in flaxseed; rather intestinal bacteria produce them from precursors in flaxseed.<sup>12,13</sup> Lignans have antioxidant activity,<sup>14</sup> and test tube and animal research suggests they may also have significant effects on the metabolism and function of the hormone estrogen.<sup>15,16,17</sup>

### Where is it found?

In addition to its presence in flaxseed oil, small amounts of ALA are also found in canola, **soy** (page 587), black currant, and walnut oils. Small amounts of lignans are present in a wide variety of foods of plant origin.

**Flaxseed and flaxseed oil has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Constipation</b> (page 137) (flaxseed) <b>Systemic lupus erythematosus</b> (page 421) (flaxseed)
★★☆	<b>High cholesterol</b> (page 223) (flaxseed)
★☆☆	<b>Benign prostatic hyperplasia (BPH)</b> (page 58) (flaxseed oil) <b>Constipation</b> (page 137) (flaxseed oil) <b>Ulcerative colitis</b> (page 433) (flaxseed)

### Who is likely to be deficient?

ALA deficiencies are possible but believed to be rare, except in infants who are fed formula that is omega-3 deficient. Lignan is not an essential nutrient, so deficiencies are not possible.

### How much is usually taken?

For promoting bowel regularity, 1 tablespoon (15 ml) of whole or ground flaxseed is taken one or two times

per day, accompanied by a full glass of water. When used to treat other health conditions, it is used in amounts of 30 to 35 grams (1 to 2 ounces) per day.

Although it is not suitable for cooking, flaxseed oil (unlike **fish oil** [page 514]) can be used in salads. Some doctors recommend that people use 1 tablespoon (15 ml) of flaxseed oil per day as a supplement in salads or on vegetables to ensure a supply of essential fatty acids. Some conversion of ALA to EPA does occur,<sup>18</sup> and this conversion can be increased by restricting the intake of other vegetable oils.<sup>19</sup>

For those who wish to replace fish oil with flaxseed oil, research suggests taking up to ten times as much ALA as EPA.<sup>20</sup> Typically, this means 7.2 grams of flaxseed oil equals 1 gram of fish oil. However, even if taken in such high amounts, flaxseed oil may not have the same effects as fish oil. But, flaxseed oil will not cause a fishy-smelling burp (a possible side effect of fish oil).

### Are there any side effects or interactions?

Flaxseed oil toxicity has not been reported. However, there is conflicting information about the effect of flaxseed oil and one of its major constituents, ALA, on **cancer** (page 87) risk.

While most test tube and animal studies suggest a possible protective role for ALA against **breast cancer** (page 65),<sup>21,22,23,24,25</sup> one animal study<sup>26</sup> and a preliminary human study<sup>27</sup> suggested increased breast cancer risk from high dietary ALA. Another preliminary human study reported that higher breast tissue levels of ALA are associated with less advanced breast cancer at the time of diagnosis.<sup>28</sup> For **prostate cancer** (page 371), a test tube study reported ALA promoted cancer cell growth,<sup>29</sup> but preliminary human studies have shown ALA to be associated with either an increased<sup>30,31</sup> or decreased risk,<sup>32</sup> or no change<sup>33</sup> at all.

Advocates of flaxseed oil speculate that a potential association between ALA and cancer may be due to the fact that meat contains ALA, thus implicating ALA when the real culprits are probably other components of meat. In some studies, however, saturated fat (and therefore probably meat) were taken into consideration, and ALA still correlated with increased risk. The associations between ALA and cancer might eventually be shown to be caused by substances found in foods rich in ALA rather than by ALA itself. However, ALA has been reported to become mutagenic (able to cause pre-cancerous changes) when heated,<sup>34</sup> which concerns some doctors.

The effect of ALA as an isolated substance, and of

flaxseed oil on the risk of cancer in humans remains unclear, with most animal and test tube studies suggesting protection, and some preliminary human trials suggesting cause for concern. It is premature to suggest that ALA and flaxseed oil will either cause or protect against human cancer at this time.

Flaxseed oil is not suitable for cooking and should be stored in an opaque, airtight container in the refrigerator or freezer. If the oil has a noticeable odor it is probably rancid and should be discarded.

As with any source of fiber, flaxseed should not be taken if there is possibility that the intestines are obstructed. People with scleroderma (systemic sclerosis) should consult a doctor before using flaxseed. Although a gradual introduction of fiber in the diet may improve bowel symptoms in some cases, there have been several reports of people with scleroderma developing severe constipation and even bowel obstruction requiring hospitalization after fiber supplementation.<sup>35</sup>

Animal research suggests that large amounts of flaxseed or lignans consumed during pregnancy might adversely affect the development of the reproductive system.<sup>36</sup> No studies have attempted to investigate whether this could be a problem in humans.

Allergic reactions to flaxseed have occasionally been reported, but are considered very uncommon.<sup>37, 38</sup>

## FLUORIDE

### What is it?

Fluoride is a binary compound of fluorine and tin.

Fluoride appears to have at least two separate mechanisms by which it prevents **tooth decay** (page 431). It affects the demineralization and remineralization of teeth in a way that makes teeth stronger.<sup>1</sup> Fluoride also reduces the production of acid by oral bacteria, protecting the teeth from damage.<sup>2</sup> Fluoride appears to have both topical and whole-body effects.<sup>3</sup>

Fluoride is one of few materials known to stimulate osteoblasts, the cells responsible for building new bone.<sup>4</sup> While exposure to fluoride clearly causes people to have denser bones, the bone that is formed may not be of optimal quality,<sup>5</sup> and may not reduce fracture risk significantly.

### Where is it found?

Fluoride is a trace mineral found in varying concentrations in foods and in water. Foods high in fluoride in-

clude fish, tea, and many different vegetables. Fluoride is added into the municipal water supply of many cities in the United States. For those people without access to fluoridated water, fluoride supplements are available in the forms of tablets and drops. These supplements are not available without a prescription. Many non-prescription dental care products contain fluoride as well, including toothpastes and mouthwashes.

**Fluoride has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Tooth decay</b> (page 431)
★☆☆	<b>Osteoporosis</b> (page 333)

### Who is likely to be deficient?

As fluoride is not considered an essential mineral, it does not have an associated deficiency state. Regardless, people living in areas with low concentrations of fluoride in the drinking water do appear to be at a higher risk of significant **tooth decay** (page 431) than those living in areas with high amounts of natural or added fluoride.

### How much is usually taken?

Drinking water containing 1 mg of fluoride per liter is considered to be roughly the optimal amount for the prevention of tooth decay. For those without access to fluoridated drinking water, chewable fluoride tablets containing 0.25 to 1 mg per day of fluoride or fluoride mouthrinses with 0.05% to 0.2% fluoride content can be used. Liquid fluoride drops are also available.

### Are there any side effects or interactions?

The risks associated with fluoridation of the public water supply have been the subject of vigorous and often heated debate since fluoridation began in 1945. Although much research has been done regarding the safety of fluoridation, a recent review found all prior studies to be of sub-optimal quality and far from definitive.<sup>6</sup>

Some,<sup>7, 8</sup> but not all,<sup>9, 10</sup> studies have found a correlation between the amount of fluoride intake and increased risk of osteoporotic fractures. The validity of the studies that found increased risk of fracture in communities with fluoridated water has been questioned by some scientists.<sup>11</sup> A pooled analysis of 29 studies on this

issue concluded that there did not appear to be an increased risk of fracture in areas of water fluoridation.<sup>12</sup>

Dental fluorosis, a brown staining of teeth due to fluoride exposure during childhood, is the best-documented adverse effect of fluoride. At a water fluoride level of 1 part per million (or 1 mg per liter), roughly 13% will have fluorosis to an aesthetically concerning degree.<sup>13</sup>

Some scientists have concluded that water fluoridation is associated with an increased risk of bone tumors,<sup>14</sup> although most others disagree.<sup>15</sup>

## FOLIC ACID

### What is it?

Folic acid is a B vitamin needed for cell replication and growth. Folic acid helps form building blocks of DNA, the body's genetic information, and building blocks of RNA, needed for protein synthesis in all cells. Therefore, rapidly growing tissues, such as those of a fetus, and rapidly regenerating cells, like red blood cells and **immune** (page 255) cells, have a high need for folic acid. Folic acid deficiency results in a form of anemia that responds quickly to folic acid supplementation.

The requirement for folic acid increases considerably during **pregnancy** (page 363).<sup>1</sup> Deficiencies of folic acid during pregnancy are associated with low birth weight and an increased incidence of **neural tube defects** (page 63) in infants.<sup>2</sup> In one study, women who were at high risk of giving birth to babies with neural tube defects were able to lower their risk by 72% by taking folic acid supplements prior to and during pregnancy.<sup>3</sup> Most doctors, many other healthcare professionals, and the March of Dimes recommend that all women of childbearing age supplement with 400 mcg per day of folic acid. Such supplementation would protect against the formation of neural tube defects during the time between conception and when pregnancy is discovered. If a woman waits until after pregnancy has been discovered to begin taking folic acid supplements, it will probably be too late to prevent a neural tube defect.

Other **birth defects** (page 63) may be prevented with folic acid supplementation as well. Women who take folic acid-containing **multivitamin supplements** (page 559) around the time they conceive may also reduce the risk of other congenital malformations, such as **heart defects** (page 63), defects of the upper lip and mouth,<sup>4</sup> **urinary tract defects** (page 63),<sup>5,6</sup> and **limb-**

**reduction defects** (page 63).<sup>7,8</sup> Rates of prevention of **cleft lip** (page 63) and cleft palate may be improved by using very large amounts of folic acid (6 mg per day).<sup>9</sup> A doctor should supervise anyone wishing to take this much folic acid.

Folic acid is needed to keep **homocysteine** (page 234) (an **amino acid** [page 465] by-product) levels in blood from rising. A growing body of evidence suggests that an elevated homocysteine level is a risk factor for **heart disease** (page 98)<sup>10</sup> and may also be linked to several other diseases. Folic acid and certain other B vitamins function as cofactors for **enzymes** (page 506) that can lower homocysteine levels. Research has shown that supplementing with folic acid reduces homocysteine levels.<sup>11</sup> Of the B vitamins with a role in homocysteine metabolism, folic acid appears to be the most important in lowering homocysteine levels for the average person.<sup>12,13</sup> A deficiency of folic acid has also been associated with peripheral vascular disease and coronary artery disease even in people with normal homocysteine levels, suggesting that the vitamin may have protective effects that extend beyond its role in maintaining normal homocysteine levels.<sup>14</sup>

In 1996, the FDA began to require that all enriched flour, rice, pasta, cornmeal, and other grain products contain 140 mcg of folic acid per 100 grams.<sup>15</sup> Among people who do not take **vitamin supplements** (page 559), this amount of food fortification has been associated with increased folic acid levels in the blood and decreased blood levels of homocysteine.<sup>16</sup> Nevertheless, evidence is mounting that the FDA-mandated level of folic acid fortification in food is inadequate to fully prevent neural tube defects.<sup>17</sup> Until fortification rates are quadrupled, women who can possibly become pregnant are advised to take a folic acid supplement of 400 mcg per day.

A diet low in folic acid has been associated with a high incidence of pre-cancerous polyps in the colon, suggesting that folic acid may prevent the development of **colon cancer** (page 123).<sup>18</sup> Two studies have shown that reduced folic acid levels are associated with an increase in the incidence of **cancer** (page 87) in people with **ulcerative colitis** (page 433)<sup>19,20</sup> and a third study showed the degree of abnormal cell growth decreases as folic acid intake increases.<sup>21</sup> Three large population studies showed that low folic acid intake is associated with an increased risk of colorectal cancer.<sup>22,23,24</sup>

In addition, decreased blood levels of folic acid are associated with an increased risk of colon cancer in women.<sup>25</sup> Long-term supplementation with folic acid

from a **multivitamin** (page 559) has been found in one large population study to be associated with a reduced risk of colon cancer. However, 15 years of supplementation was necessary before a significant reduction in colon-cancer risk became apparent. In that study, folic acid from dietary sources alone was associated with a modest reduction in the risk of colon cancer.<sup>26</sup>

Total folic acid intake was not associated with overall risk of **breast cancer** (page 65) in preliminary studies.<sup>27,28</sup> However, among women who consume at least one alcoholic beverage per day, the risk of breast cancer appears to be highest among those with low folic acid intake. Current use of a multivitamin supplement has also been associated with lower breast cancer risk among women who consume at least 1.5 alcoholic beverages per day, compared with those who never use a multivitamin supplement.

### Where is it found?

Beans, leafy green vegetables, citrus fruits, beets, wheat germ, and meat are good sources of folic acid.

**Folic acid has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Birth defects prevention</b> (page 63) <b>Depression</b> (page 145) <b>Gingivitis (periodontal disease)</b> (page 203) (rinse only) <b>High homocysteine</b> (page 235) (in combination with <b>vitamin B<sub>6</sub></b> [page 600] and <b>vitamin B<sub>12</sub></b> [page 601]) <b>Pap smear (abnormal)</b> (page 3) (in women taking oral contraceptives) <b>Pregnancy and postpartum support</b> (page 363) <b>Schizophrenia</b> (page 393) (for deficiency)
★★☆	<b>Anemia</b> (page 25) (for thalassemia if deficient) <b>Atherosclerosis</b> (page 38) <b>Breast cancer</b> (page 65) (reduces risk in women who consume alcohol) <b>Canker sores</b> (page 90) (for deficiency only) <b>Celiac disease</b> (page 102) (for deficiency only) <b>Colon cancer</b> (page 123) (prevention) <b>Heart attack</b> (page 212) <b>Preeclampsia</b> (page 361) <b>Sickle cell anemia</b> (page 403) (for lowering <b>homocysteine</b> (page 235) levels) <b>Skin ulcers</b> (page 409) <b>Ulcerative colitis</b> (page 433)

Rating	Health Concerns
★☆☆	<b>Alzheimer's disease</b> (page 19) <b>Bipolar disorder/Manic depression</b> (page 61) <b>Crohn's disease</b> (page 141) <b>Dermatitis herpetiformis</b> (page 151) (for deficiency) <b>Diarrhea</b> (page 163) <b>Down's syndrome</b> (page 169) <b>Epilepsy</b> (page 183) <b>Gingivitis (periodontal disease)</b> (page 203) (pill) <b>Gout</b> (page 208) <b>HIV support</b> (page 239) <b>Lung cancer</b> (page 298) (reduces risk) <b>Osteoporosis</b> (page 333) <b>Peripheral vascular disease</b> (page 352) <b>Psoriasis</b> (page 379) <b>Restless legs syndrome</b> (page 384) <b>Seborrheic dermatitis</b> (page 400) <b>Stroke</b> (page 419) (for high homocysteine only) <b>Vitiligo</b> (page 443)

### Who is likely to be deficient?

Many people consume less than the recommended amount of folic acid. Scientists have found that people with **heart disease** (page 98) commonly have elevated blood levels of **homocysteine** (page 235), a laboratory test abnormality often controllable with folic acid supplements. This suggests that many people in Western societies have a mild folic acid deficiency. In fact, it has been suggested that increasing folic acid intake could prevent an estimated 13,500 deaths from cardiovascular diseases each year.<sup>29</sup>

Folic acid deficiency has also been common in **alcoholics** (page 12), people living at poverty level, those with **malabsorption disorders** (page 304) or liver disease (e.g., **cirrhosis** [page 290]), and women taking the birth control pill. Recently, elderly people with hearing loss have been reported to be much more likely to be folic acid deficient than healthy elderly people.<sup>30</sup> A variety of prescription drugs including cimetidine, antacids, some **anticancer** (page 87) drugs, triamterene, sulfasalazine, and anticonvulsants interfere with folic acid.

Deficiency of folic acid can be precipitated by situations wherein the body requires greater than normal amounts of the vitamin, such as **pregnancy** (page 363), infancy, leukemia, exfoliative dermatitis, and diseases that cause the destruction of blood cells.<sup>31</sup>

The relationship between folic acid and prevention of **neural tube defects** (page 63) is partly thought to re-

sult from the high incidence of folate deficiency in many societies. To protect against neural tube defects, the U.S. Food and Drug Administration has mandated that some grain products provide supplemental folic acid at a level expected to increase the dietary intake by an average of 100 mcg per day per person. As a result of folic acid added to the food supply, fewer Americans will be depleted compared with the past. In 1999, scientific evidence began to demonstrate that the folic acid added to the U.S. food supply was having positive effects, including a partial lowering of homocysteine levels.<sup>32</sup> In the same year, however, a report from the North Carolina Birth Defects Monitoring Program suggested the current level of folic acid fortification has not reduced the incidence of neural-tube defects.<sup>33</sup> Many doctors and the Centers for Disease Control in Atlanta<sup>34</sup> believe that optimal levels of folic acid intake may still be higher than the amount now being added to food by several hundred micrograms per day. A low blood level of folate has also been associated with an increased risk of miscarriage.<sup>35</sup>

People with kidney failure have an increased risk of folic acid deficiency.<sup>36</sup> Recipients of kidney transplants often have elevated homocysteine levels, which may respond to supplementation with folic acid.<sup>37</sup> The usual recommended amount of 400 mcg per day may not be enough for these people, however. Larger amounts (up to 2.4 mg per day) may produce a better outcome, according to one double-blind trial.<sup>38</sup>

Folate deficiency is more prevalent among elderly African American women than among elderly white women.<sup>39</sup>

#### Which form is best?

Folic acid naturally found in food is much less available to the body compared with synthetic folic acid found both in **supplements** (page 559) and added to grain products in the United States. Women with a recent history of giving birth to babies with **neural tube defects** (page 63) participated in a study to determine which form of folic acid is best absorbed—dietary folic acid or folic acid from supplements.<sup>40</sup> They received either orange juice containing 400 mcg of folic acid per day or a supplement containing the same amount. Overall, the supplement folic acid was better absorbed than the folic acid from orange juice.

#### How much is usually taken?

Many doctors recommend that all women who are or who could become **pregnant** (page 363) take 400 mcg

per day in order to reduce the risk of **birth defects** (page 63). Some doctors also extend this recommendation to other people in an attempt to reduce the risk of **heart disease** (page 98) by lowering **homocysteine** (page 235) levels. Since the FDA mandated addition of folic acid to grain products, many people who eat grains have followed the new recommendation of supplementing only 100 mcg of folic acid per day. However, studies have found that this amount of folic acid is inadequate to maintain normal folate levels in a significant percentage of the groups assessed.<sup>41</sup> It now appears that, for pregnant women, supplementing with at least 300 mcg (and optimally 400 mcg) of folic acid per day is sufficient to prevent a folate deficiency, even if dietary intake is low.

#### Are there any side effects or interactions?

Folic acid is not generally associated with side effects.<sup>42</sup> However, folic acid supplementation can interfere with the laboratory diagnosis of **vitamin B<sub>12</sub>** (page 601) deficiency, possibly allowing the deficiency to progress undetected to the point of irreversible nerve damage.<sup>43</sup> Although vitamin B<sub>12</sub> deficiency is uncommon, no one should supplement with 1,000 mcg or more of folic acid without consulting a doctor.

Vitamin B<sub>12</sub> deficiencies often occur without anemia (even in people who do not take folic acid supplements). Some doctors do not know that the absence of anemia does not rule out a B<sub>12</sub> deficiency. If this confusion delays diagnosis of a vitamin B<sub>12</sub> deficiency, the patient could be injured, sometimes permanently. This problem is rare and should not happen with doctors knowledgeable in this area using correct testing procedures.

Folic acid is needed by the body to utilize vitamin B<sub>12</sub>. **Proteolytic enzymes** (page 506) inhibit folic acid absorption.<sup>44</sup> People taking proteolytic enzymes are advised to supplement with folic acid.

## FRUCTO-OLIGOSACCHARIDES (FOS) AND OTHER OLIGOSACCHARIDES

#### What is it?

The term “oligosaccharide” refers to a short chain of sugar molecules (“oligo” means “few” and “saccharide” means “sugar.”) Fructo-oligosaccharides (FOS) and in-

ulin, which are found in many vegetables, consist of short chains of fructose molecules. Galacto-oligosaccharides (GOS), which also occur naturally, consist of short chains of galactose molecules. These compounds can be only partially digested by humans.<sup>1, 2, 3, 4</sup> When oligosaccharides are consumed, the undigested portion serves as food for “friendly” bacteria, such as **Bifidobacteria** (page 575) and **Lactobacillus** (page 575) species.

Clinical studies have shown that administering FOS, GOS, or inulin can increase the number of these friendly bacteria in the colon while simultaneously reducing the population of harmful bacteria.<sup>5, 6, 7, 8, 9</sup> Other benefits noted with FOS, GOS, or inulin supplementation include increased production of beneficial short-chain fatty acids such as butyrate, increased absorption of **calcium** (page 483) and **magnesium** (page 551), and improved elimination of toxic compounds.<sup>10, 11</sup>

Because FOS, GOS, and inulin improve colon function and increase the number of friendly bacteria, one might expect these compounds would help relieve the symptoms of **irritable bowel syndrome** (page 280). However, a double-blind trial found no clear benefit with FOS supplementation (2 grams three times daily) in patients with this condition.<sup>12</sup> Experimental studies with FOS in animals suggest a possible benefit in lowering blood sugar levels in people with **diabetes** (page 152) and in reducing elevated blood **cholesterol** (page 223) and **triglyceride** (page 235) levels.<sup>13</sup>

In a double-blind trial of middle-aged men and women with elevated cholesterol and triglyceride levels, supplementation with inulin (10 grams per day for eight weeks) significantly reduced insulin concentrations (suggesting an improvement in blood-glucose control) and significantly lowered triglyceride levels.<sup>14</sup> In a preliminary trial, administration of FOS (8 grams per day for two weeks) significantly lowered fasting blood-sugar levels and serum total-cholesterol levels in patients with type 2 (non-insulin-dependent) diabetes.<sup>15</sup> However, in another trial, people with type 2 diabetes supplementing with FOS (15 grams per day) for 20 days found no effect on blood-glucose or lipid levels.<sup>16</sup> In addition, double-blind trials of healthy people showed that supplementing with FOS or GOS for eight weeks had no effect on blood-sugar levels, insulin secretion, or blood lipids.<sup>17, 18</sup> Because of these conflicting results, more research is needed to determine the effect of FOS and inulin on diabetes and lipid levels.

Several double-blind trials have looked at the ability of FOS or inulin to lower blood cholesterol and triglyc-

eride levels. These trials have shown that in people with elevated total **cholesterol** (page 223) or **triglyceride** (page 235) levels, including people with type 2 (adult onset) **diabetes** (page 152), FOS or inulin (in amounts ranging from 8 to 20 grams daily) produced significant reductions in triglyceride levels. However, the effect on cholesterol levels was inconsistent.<sup>19, 20, 21, 22</sup> In people with normal or low cholesterol or triglyceride levels, FOS or inulin produced little effect.<sup>23, 24, 25</sup>

### Where is it found?

FOS and inulin are found naturally in Jerusalem artichoke, **burdock** (page 648), chicory, leeks, onions, and asparagus. FOS products derived from chicory root contain significant quantities of inulin,<sup>26</sup> a fiber widely distributed in fruits, vegetables and plants, which is classified as a food ingredient (not as an additive) and is considered to be safe to eat.<sup>27</sup> In fact, inulin is a significant part of the daily diet of most of the world's population.<sup>28</sup> FOS can also be synthesized by **enzymes** (page 506) of the fungus *Apergillus niger* acting on sucrose. GOS is naturally found in soybeans and can be synthesized from lactose (milk sugar). FOS, GOS, and inulin are available as nutritional supplements in capsules, tablets, and as a powder.

**FOS, GOS, and inulin have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Elevated triglyceride levels</b> (page 235)
★☆☆	<b>Diabetes</b> (page 152)
	<b>Pre- and post-surgery health</b> (page 357)

### Who is likely to be deficient?

As FOS, GOS, and inulin are not essential nutrients, no deficiency state exists.

### How much is usually taken?

The average daily intake of oligosaccharides by people in the United States is estimated to be about 800 to 1,000 mg. For the promotion of healthy bacterial flora, the usual recommendation for FOS, GOS, or inulin is 2,000 to 3,000 mg per day with meals. In the studies on **diabetes** (page 152) and high blood lipids (**cholesterol** [page 223] and **triglycerides** [page 235]), amounts ranged from 8 to 20 grams per day.

### **Are there any side effects or interactions?**

Generally, oligosaccharides are well tolerated. Some people reported increased **flatulence** (page 260) in some of the studies. At higher levels of intake, that is, in excess of 40 grams per day, FOS and the other oligosaccharides may induce **diarrhea** (page 163).

There is a report of a 39-year old man having a life-threatening allergic reaction after consuming high amounts of inulin from multiple sources, including FOS.<sup>29</sup> **Allergy** (page 14) to inulin in this person was confirmed by laboratory tests. Such sensitivities are extremely rare. People with a confirmed sensitivity to inulin should probably avoid FOS.

## FUMARIC ACID

### **What is it?**

Fumaric acid is related to malic acid, and, like **malic acid** (page 552), it is involved in the production of energy (in the form of adenosine triphosphate [ATP]) from food.

### **Where is it found?**

Fumaric acid is formed in the skin during exposure to sunlight, as well as being available as an oral supplement and as a preparation for topical use.

**Fumaric acid has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Psoriasis</b> (page 379)

### **Who is likely to be deficient?**

No deficiencies of fumaric acid have been reported. However, some doctors suggest that people with **psoriasis** (page 379) may have a biochemical defect that interferes with adequate fumaric acid production in the skin.

### **How much is usually taken?**

Only the esterified forms of fumaric acid are used therapeutically, such as fumaric acid monoethylester or fumaric acid di-methylester. Healthy people do not need to supplement with fumaric acid. Those using this sub-

stance (either orally or topically) should work with a dermatologist, since determining the optimal intake should be done on an individual basis. Even under these circumstances, supplementing should be started with small amounts (60–100 mg per day) and increased gradually over several weeks until an effect is noted.

### **Are there any side effects or interactions?**

Kidney disorders have been reported in people taking fumaric acid esters, possibly due to taking large amounts too quickly.<sup>1, 2</sup> Most studies have reported **gastrointestinal upset** (page 195) and skin flushing as common side effects; some have also found decreased white blood cell counts with prolonged use.<sup>3, 4</sup>

## GABA (GAMMA-AMINO BUTYRIC ACID)

### **What is it?**

GABA is a natural calming and anti-epileptic agent in the brain that is manufactured from the amino acid **glutamine** (page 530) and glucose.

Since GABA does not cross the blood-brain barrier very well (i.e., it cannot be transported efficiently into the brain from the bloodstream), virtually all of the GABA found in the brain is manufactured there.<sup>1</sup> For that reason, supplemental GABA would not be expected to increase levels of GABA in the brain. Two doctors have reported that GABA is beneficial in the treatment of a variety of brain disorders, including **epilepsy** (page 183) and **schizophrenia** (page 393).<sup>2</sup> However, those reports have not been substantiated with clinical trials. High intake of GABA was shown to produce a significant increase in plasma growth-hormone levels (single administration of 5,000 mg) and prolactin (daily administration of 18,000 mg for four days) in one human study<sup>3</sup> but the clinical significance of these observations is not clear.

### **Where is it found?**

GABA is found as a nutritional supplement, primarily in capsules and tablets.

### **Who is likely to be deficient?**

Some people with **anxiety** (page 30), panic disorders, and **depression** (page 145) may not manufacture sufficient levels of GABA.

**How much is usually taken?**

Some doctors recommend GABA in the amount of 200 mg four times daily.

**Are there any side effects or interactions?**

The safety of GABA supplementation has not been demonstrated in human trials.

## GAMMA ORYZANOL

**What is it?**

Gamma oryzanol is a naturally occurring mixture of plant chemicals called sterols and ferulic acid esters.

Some evidence suggests that gamma oryzanol increases testosterone levels, stimulates the release of endorphins (pain-relieving substances made in the body), and promotes the growth of lean muscle tissue.<sup>1</sup> Supplementation with gamma oryzanol for nine weeks did not influence **exercise performance** (page 43) in male weight lifters.<sup>2</sup>

**Where is it found?**

Gamma oryzanol is a natural component of rice bran, corn, and barley oils. Gamma oryzanol is also available as a supplement.

**Gamma oryzanol has been used in connection with the following condition** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Gastritis (page 195)
★★☆	Athletic performance (page 43)

**Who is likely to be deficient?**

Since gamma oryzanol is not an essential nutrient, it is not associated with a deficiency state.

**How much is usually taken?**

Much of the human research with gamma oryzanol used 300 mg per day. Healthy people do not appear to need this supplement.

**Are there any side effects or interactions?**

Some research suggests that gamma oryzanol taken in moderately high amounts (up to 600 mg per day) for

several months can cause dry mouth, sleepiness, hot flushes, irritability, and light headedness in some individuals.<sup>3</sup>

## GLANDULAR EXTRACTS

**See also:** **Adrenal Extracts** (page 462), **Liver Extracts** (page 547), **Spleen Extracts** (page 588), **Thymus Extracts** (page 591), **Thyroid Extracts** (page 592)

**What is it?**

A gland is defined as a secretory organ (i.e., an organ that secretes substances into the bloodstream or elsewhere in the body). The internal secretory organs of the body are called endocrine glands. These ductless glands secrete hormones directly into the blood stream. The glands that are known to have endocrine function include the pineal, pituitary, thyroid, parathyroid, thymus, adrenal, pancreas, and gonads (testes and ovaries). Although not technically glands, other organs of the body are commonly also referred to as "glandulars" when they are taken as supplements. For example, tissue extracts of the heart, spleen, prostate, uterus, brain, and other tissues are often used in so-called "glandular therapy," along with extracts from pineal, pituitary, thyroid, parathyroid, thymus, adrenal, pancreas, and gonads. Glandular therapy refers to the use of animal tissues to try to enhance the function of, or mimic the effect of, the corresponding human tissue.

There are two basic concepts upon which glandular therapy is based. The first is that "like heals like." For example, feeding prostate tissue might, in theory, help the body's prostate gland heal or function better. The second concept is that ingestion of certain glandular tissues will provide the body with hormones or other biologically active substances that are normally secreted by that gland. For almost as long as historic records have been kept, glandular therapy has been an important form of medicine. While ancient glandular therapy usually involved the use of fresh, whole glands, modern glandular therapy primarily involves the use of concentrated glandular extracts.

While it is well established that some glandular preparations may be effective orally because of active hormone or enzyme content (e.g., thyroid and pancreatic-enzyme preparations), the effects of other commercially available glandular products are not known as they have not been sufficiently studied.

Detractors of glandular therapy often claim that when a glandular product is consumed, its potentially active components are destroyed by **digestive enzymes** (page 506) in the gastrointestinal tract before they can be absorbed into the body. Therefore, orally administered glandular products cannot be effective. However, there is now much evidence that, under normal conditions, some proteins, enzymes, and other large molecules can and do pass intact from the human gut into the bloodstream.<sup>1, 2, 3, 4</sup>

### Where is it found?

Most glandular products are derived from beef (bovine) sources, with the exception of pancreatic extracts, which are most often derived from pork (porcine). The four most widely known methods of processing are the azeotropic method, salt precipitation, freeze-drying, and predigestion.

The azeotropic method begins by quick-freezing the material at well below 0 degrees F, and then washing the material with a powerful solvent (ethylene dichloride) to remove the fatty tissue. The solvent is then distilled off and the material is dried and ground into a powder so that it can be placed in tablets or capsules. Although the azeotropic method aids in the removal of fat-stored toxins (like pesticides) and toxic heavy metals, it also removes fat-soluble hormones, enzymes, essential fatty acids, and other potentially beneficial materials.

The salt precipitation method involves the maceration of fresh glandular material in a salt and water solution. Like the azeotropic method, this process also allows the fat-soluble material to be separated out. The benefit of the salt precipitation method is that no toxic solvents are used to remove the fatty material. The down side is that the salt content can be very high, and that some of the potentially beneficial constituents may be removed.

The freeze-drying process involves quickly freezing the glandular material at temperatures 40 to 60 degrees below 0 degrees F and then placing the material into a vacuum chamber, which removes the water by direct vaporization from its frozen state—hence the term freeze-drying. The benefits of freeze-drying are that it preserves more of the unaltered protein and enzymes as well as all of the fat-soluble components. Since the fat is not removed, potentially harmful contaminants that accumulate in fat tissue may remain in the product. It is

therefore critical that the glands be derived from livestock that have grazed on open ranges that are not sprayed with pesticides or herbicides. The animals should also be free of antibiotics, synthetic hormones, and infection.

The predigestion method employs the aid of plant and animal enzymes to partially digest or hydrolyze the glandular material. The partially digested material is then passed through a series of filtrations to separate out fat-soluble and large molecules. The purified material is then freeze-dried. This method of extraction is thought to be ideal for certain glandulars, such as liver and thymus, where the polypeptide (small proteins) and other water-soluble fractions are desired.

### Who is likely to be deficient?

As glandulars are not essential nutrients, no deficiency states exist.

### How much is usually taken?

The recommended amount may vary according to the potency and method of preparation of the particular product. Please consult the label on the specific glandular product.

### Are there any side effects or interactions?

Refer to the specific glandular product.

## GLUCOMANNAN

### What is it?

Glucomannan is a water-soluble dietary **fiber** (page 512) that is derived from konjac root (*Amorphophallus konjac*). Like other forms of dietary fiber, glucomannan is considered a “bulk-forming laxative.” Glucomannan promotes a larger, bulkier stool that passes through the colon more easily and requires less pressure—and subsequently less straining—to expel.

Good results have been noted in preliminary<sup>1</sup> and double-blind studies<sup>2, 3, 4, 5</sup> of glucomannan for the treatment of **constipation** (page 137). In constipated individuals, glucomannan and other bulk-forming laxatives generally help produce a bowel movement within 12 to 24 hours.<sup>6</sup> The use of glucomannan for **diverticular disease** (page 168) of the colon has also been studied in preliminary research; about one-third

to one-half of the subjects were found to benefit from glucomannan.<sup>7</sup>

Glucomannan delays stomach emptying, leading to a more gradual absorption of dietary sugar; this effect can reduce the elevation of blood sugar levels that is typical after a meal.<sup>8</sup> Controlled studies have found that after-meal blood sugar levels are lower in people with diabetes given glucomannan in their food,<sup>9</sup> and overall diabetic control is improved with glucomannan-enriched diets according to preliminary<sup>10</sup> and controlled<sup>11, 12</sup> trials. One preliminary report suggested that glucomannan may also be helpful in pregnancy-related diabetes.<sup>13</sup> One double-blind study reported that glucomannan (8–13 grams per day) stabilized blood sugar in people with the **insulin resistance syndrome** (page 273) (syndrome X).<sup>14</sup> In a preliminary study,<sup>15</sup> addition of either 2.6 or 5.2 grams of glucomannan to a meal prevented **hypoglycemia** (page 251) in adults with previous stomach surgery; a similar study of children produced inconsistent results.<sup>16</sup>

Like other soluble fibers, glucomannan can bind to bile acids in the gut and carry them out of the body in the feces, which requires the body to convert more cholesterol into bile acids.<sup>17</sup> This can result in the lowering of blood **cholesterol** (page 223) and other blood fats. Controlled<sup>18, 19</sup> and double-blind<sup>20, 21</sup> studies have shown that supplementation with several grams per day of glucomannan significantly reduced total blood cholesterol, LDL (“bad”) cholesterol, and **triglycerides** (page 235), and in some cases raised HDL (“good”) cholesterol. One double-blind study reported that glucomannan (8–13 grams per day) lowered total and LDL cholesterol in people with the insulin resistance syndrome.<sup>22</sup>

Glucomannan may help **weight loss** (page 446) by occupying space in the stomach, thereby making a person feel full. One double-blind study reported weight loss averaging 5.5 pounds in adults when one gram of glucomannan was taken with a cup of water one hour before each meal for eight weeks.<sup>23</sup> However, a similar study of overweight children found that glucomannan was not significantly more effective than a placebo.<sup>24</sup> Other controlled studies have found that glucomannan improves the results of weight loss diets in overweight adults<sup>25</sup> and children.<sup>26</sup>

#### Where is it found?

Glucomannan is a purified fiber from konjac root that is available as a bulk powder or in hard-gelatin capsules.

Whether any foods contain significant amounts of glucomannan is unclear.

**Glucomannan has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Constipation</b> (page 157) <b>Diabetes</b> (page 152) <b>High blood cholesterol</b> (page 246) <b>Insulin resistance syndrome</b> (page 273) (Syndrome X)
★★☆	<b>Obesity</b> (page 446)
★☆☆	<b>Diverticular disease</b> (page 168) <b>Hypoglycemia</b> (page 251)

#### Who is likely to be deficient?

As glucomannan is not an essential nutrient, no deficiency state exists.

#### How much is usually taken?

The amount of glucomannan shown to be effective as a laxative is 3–4 grams per day.<sup>27, 28</sup> Effective amounts for lowering blood cholesterol have been 4–13 grams per day.<sup>29, 30, 31</sup> For controlling blood sugar, 500–700 mg of glucomannan per 100 calories in the diet has been used successfully in controlled research.<sup>32, 33</sup> For weight loss, 1 to 3 grams before each meal has been effective.<sup>34, 35</sup> When using glucomannan and other dietary fiber supplements, it is best to start out with a small amount and increase gradually. It is recommended to drink at least 8 ounces of water each time any bulk-forming laxative, including glucomannan, is taken.

#### Are there any side effects or interactions?

People with any disorder of the esophagus (the tube leading from the mouth to the stomach) should not take any fiber supplement in a pill form, as the supplement may expand in the esophagus and lead to obstruction.<sup>36</sup> Preliminary reports in humans, as well as animal research, suggest that some people may be sensitive to inhaled glucomannan powder.<sup>37</sup>

Since intestinal bacteria ferment water-soluble fibers, a great deal of intestinal gas may be produced in individuals not accustomed to a high fiber diet, leading to flatulence and abdominal discomfort.

## GLUCOSAMINE

### What is it?

Glucosamine is an important building block needed by the body to manufacture specialized molecules called glycosaminoglycans, found in cartilage.

Glucosamine is almost exclusively researched and used for the treatment of **osteoarthritis** (page 328) (OA).

### Where is it found?

Glucosamine is not present in significant amounts in most diets. Supplemental sources are derived from the shells of shrimp, lobster, and crab, or may be synthesized.

**Glucosamine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Osteoarthritis</b> (page 328) (glucosamine sulfate)
★★☆	Knee pain (glucosamine HCl)

### Who is likely to be deficient?

A glucosamine deficiency in humans has not been reported.

### Which form is best?

Glucosamine is available in several forms. The glucosamine sulfate (GS) form (stabilized with a mineral salt) is the only form clearly shown in clinical trials to be effective for **osteoarthritis** (page 328). For this reason, it is the preferred form.

GS is stabilized with one of two mineral salts: sodium chloride (NaCl) or potassium chloride (KCl).<sup>1, 2</sup> Although they both appear to effectively stabilize GS, the use of KCl as a stabilizer seems preferable since the average Western diet already provides far too much salt (NaCl) and not enough **potassium** (page 572). However, most of the research has been done with the NaCl-stabilized form.

Glucosamine hydrochloride (GH) has been widely available as a dietary supplement for years, but only

one trial has evaluated this form of glucosamine as a single remedy for OA.<sup>3</sup> This trial found only minor significant benefits from 1,500 mg per day of GH for eight weeks, in people with osteoarthritis of the knee who were also taking up to 4,000 mg/day of acetaminophen. To more fairly evaluate the effects of GH, future research should involve people not taking pain-relieving medication.

Another form of glucosamine, **N-acetyl-glucosamine (NAG)** (page 564), has not been studied in people with **osteoarthritis** (page 328).

### How much is usually taken?

Healthy people do not need to routinely supplement with glucosamine. Most research with people who have **osteoarthritis** (page 328), uses 500 mg three times per day of GS. Appropriate amounts for other conditions are not known.

### Are there any side effects or interactions?

At the amount most frequently taken by adults—500 mg three times per day of GS—adverse effects have been limited to mild reversible gastrointestinal side effects. In one trial, people with **peptic ulcers** (page 349) and those taking diuretic drugs were more likely to experience side effects.<sup>4</sup>

Animal research has raised the possibility that glucosamine could contribute to **insulin resistance** (page 273).<sup>5, 6</sup> This effect might theoretically result from the ability of glucosamine to interfere with an **enzyme** (page 506) needed to regulate blood sugar levels.<sup>7</sup> However, available evidence does not suggest that taking glucosamine supplements will trigger or aggravate insulin resistance or **high blood sugar** (page 251).<sup>8</sup> Two large, 3-year controlled trials found that people taking GS had either slightly *lower* blood glucose levels or no change in blood sugar levels, compared with people taking placebo.<sup>9, 10</sup> Until more is known, people taking glucosamine supplements for long periods may wish to have their blood sugar levels checked; people with **diabetes** (page 152) should consult with a doctor before taking glucosamine and should have blood sugar levels monitored if they are taking glucosamine.

In 1999 the first case of an **allergic reaction** (page 14) to oral GS was reported.<sup>11</sup> Allergic reactions to this supplement appear to be rare.

Some GS is processed with sodium chloride (table salt), which is restricted in some diets (particularly for people with **high blood pressure** [page 246]).

The theory that GS and **chondroitin sulfate** (page 492) work synergistically in the treatment of **osteoarthritis** (page 328) remains unproven.

## GLUCOSAMINE/ CHONDROITIN

Glucosamine and chondroitin are building blocks of connective tissue and are key components of the joints.

For detailed discussions of these nutrients, please see the individual articles for **glucosamine sulfate** (page 528) and **chondroitin sulfate** (page 492).

Glucosamine is a simple molecule that is available as a supplement in several forms: glucosamine sulfate, glucosamine hydrochloride and N-acetyl-glucosamine (**NAG** [page 564]). The glucosamine sulfate (GS) form (stabilized with a mineral salt, such as sodium chloride or potassium chloride) is the only form consistently shown in clinical trials to be effective for people with **osteoarthritis** (OA [page 328]).

**Chondroitin sulfate** (CS [page 492]) is a much larger and more complex molecule than GS. Like glucosamine, it is a major constituent of cartilage and has been the subject of many clinical trials. CS supplementation has proven to be an effective treatment for people with OA.

When to take glucosamine, chondroitin sulfate, or both: The popular idea that GS is clinically “preferred” over CS, or that CS is “not necessary,”<sup>1</sup> has not been examined (let alone supported) by appropriate comparative research. An analysis of controlled clinical trials evaluated the independent effects of GS and CS in the treatment of OA.<sup>2</sup> The authors concluded that the overall efficacy in trials of CS for people with OA exceeded the overall efficacy of GS for people with that condition. However, more than one-third of CS supplements have been reported to contain less than 40% of the amount of CS listed on the label.<sup>3</sup> Moreover, no single clinical trial has compared the effects of the two supplements.

Many people with osteoarthritis take combinations of CS and GS or glucosamine HCl. This practice may be based on the suggestion, made in a best-selling book,<sup>4</sup> that GS and CS in combination have stronger effects than either supplement alone. Although this idea may sound appealing, and may be harmless, it is based only on anecdotes and hypotheses. The theory that GS and CS work synergistically in the treatment of osteoarthritis remains unproven. To date, no clinical trials

have compared glucosamine/chondroitin combinations with either of the supplements taken individually.

One preliminary trial found that the combination of glucosamine HCl (1,600 mg per day), CS (1,200 mg per day), and calcium ascorbate (1,000 mg per day) was effective at reducing joint noise, **pain** (page 338), and swelling in people with osteoarthritis of the temporomandibular joint (TMJ, or jaw joint).<sup>5</sup> However, this study was not well controlled and the outcomes measured were highly subjective. Moreover, participants in this study were allowed to use aspirin and ibuprofen, so the exact effects of the nutrient combination cannot be accurately assessed.

Similarly, the combination of glucosamine HCl (1,500 mg per day), CS (1,200 mg per day), and manganese ascorbate (228 mg per day) was evaluated in a double-blind trial and was associated with significant symptom reduction and improvement on x-ray for osteoarthritis of the knee (less so for spine). However, subjects were allowed to use acetaminophen for pain, and comparative effects of a glucosamine HCl/chondroitin sulfate combination and the individual nutrients were not examined.<sup>6</sup>

## GLUTAMIC ACID

### What is it?

Glutamic acid (glutamate) is an **amino acid** (page 465) used by the body to build proteins. Glutamate is the most common excitatory (stimulating) neurotransmitter in the central nervous system.

Under normal circumstances, humans are able to meet bodily glutamate requirements either from the diet or by making it from precursor molecules. Although **glutamine** (page 530) and glutamic acid have similar names, they are structurally different.

The fluid produced by the prostate gland contains significant amounts of glutamic acid, and this amino acid may play a role in normal function of the prostate. In one study, symptoms of **benign prostatic hyperplasia** (BPH [page 58]) were improved in a group of 45 men taking 780 mg of glutamic acid per day for two weeks and then 390 mg for the next two and a half months in combination with equal amounts of the amino acids, **alanine** (page 463) and **glycine** (page 532),<sup>1</sup> an effect also reported by other researchers.<sup>2</sup>

Glutamic acid may have protective effects on the heart muscle in people with **heart disease** (page 98).

Intravenous injections of glutamic acid (as monosodium glutamate) have been shown to increase exercise tolerance and heart function in people with stable **angina pectoris** (page 27).<sup>3</sup>

### Where is it found?

Sources of glutamic acid include high-protein foods, such as meat, poultry, fish, eggs, and dairy products. Some protein-rich plant foods also supply glutamic acid.

**Glutamic acid has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Benign prostatic hyperplasia</b> (page 58)
★★☆	Heart surgery (support)

### Who is likely to be deficient?

Most food sources of protein supply glutamic acid, so only a person deficient in protein would become deficient in glutamic acid.<sup>4</sup>

### How much is usually taken?

Healthy people do not need to take glutamic acid as a supplement; for those who do use this **amino acid** (page 465), appropriate amounts should be determined with the consultation of a physician.

### Are there any side effects or interactions?

Glutamic acid is generally free of side effects for the vast majority of people who take it; however, people with **kidney** (page 284) or liver disease should not consume high intakes of **amino acids** (page 465) without consulting a healthcare professional. Because over stimulation of glutamate receptors is thought to be a possible cause of certain neurological diseases (e.g., amyotrophic lateral sclerosis [Lou Gehrig's disease] and **epilepsy** [page 183]), people with a neurological disease should consult of physician before supplementing with glutamate.

Monosodium glutamate (MSG), the form of glutamic acid that is used as a flavor enhancer, has been reported in anecdotal studies to have a number of different adverse effects (including headache, fatigue, and **depression** [page 145]). However, controlled trials have failed to confirm that MSG causes these side ef-

fects, and the safety of this compound remains controversial.

## GLUTAMINE

### What is it?

Glutamine is the most abundant **amino acid** (page 465) (protein building block) in the body and is involved in more metabolic processes than any other amino acid. Glutamine is converted to glucose when more glucose is required by the body as an energy source. It serves as a source of fuel for cells lining the intestines. Without it, these cells waste away. It is also used by white blood cells and is important for **immune function** (page 255).

In animal research, glutamine has anti-inflammatory effects. Glutamine in combination with **N-acetyl cysteine** (page 562) promotes the synthesis of **glutathione** (page 531), a naturally occurring **antioxidant** (page 467) that is believed to be protective in people with **HIV infection** (page 239).<sup>1</sup> Evidence indicates that intravenous glutamine supplementation increases the survival rate of critically ill people.<sup>2</sup>

### Where is it found?

Glutamine is found in many foods high in protein, such as fish, meat, beans, and dairy products.

**Glutamine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Pre- and post-surgery health</b> (page 357)
★★☆	<b>Athletic performance</b> (page 43) (for prevention of post exercise infection in performance athletes) <b>Diarrhea</b> (page 163) <b>HIV support</b> (page 239) (in combination with <b>arginine</b> [page 467] and <b>HMB</b> [page 534]) <b>Immune function</b> (page 255) (for post-exercise infection prevention in endurance athletes) <b>Infection</b> (page 265) (for prevention of post exercise infection in performance athletes)
★☆☆	<b>Alcohol withdrawal support</b> (page 12) <b>Gastritis</b> (page 195) <b>HIV support</b> (page 239) <b>Peptic ulcer</b> (page 349)

### Who is likely to be deficient?

Few healthy people are glutamine deficient, in part because the body makes its own. During fasting, starvation, **cirrhosis** (page 290), critical illnesses in general, and weight loss associated with **AIDS** (page 239) and **cancer** (page 87), however, deficiencies often develop.

### How much is usually taken?

Healthy people do not need to supplement with glutamine. A physician should be consulted for the supplemental use of glutamine for the support of serious health conditions.

### Are there any side effects or interactions?

No significant side effects have been reported in glutamine studies.

## GLUTATHIONE

### What is it?

Glutathione is a small protein composed of three **amino acids** (page 465): **cysteine** (page 502), **glutamic acid** (page 529), and **glycine** (page 532).

Glutathione is involved in detoxification—it binds to toxins, such as heavy metals, solvents, and pesticides, and transforms them into a form that can be excreted in urine or bile. Glutathione is also an important antioxidant. In preliminary research, dietary glutathione intake from fruit and raw vegetables has been associated with protection against some forms of **cancer** (page 87).<sup>1, 2</sup> Glutathione has also inhibited cancer in test tube<sup>3</sup> and animal studies.<sup>4</sup> In preliminary research, higher glutathione levels have also been associated with good health in older adults.<sup>5</sup>

Glutathione supplements appear to be efficiently absorbed in rats.<sup>6, 7</sup> However, the same may not be true for glutathione supplements in humans. For example, when seven healthy people were given a single application of up to 3,000 mg of glutathione, there was no increase in blood glutathione levels.<sup>8</sup> The authors of the study concluded “it is not feasible to increase circulating glutathione to a clinically beneficial extent by the oral administrating of a single application of 3,000 mg of glutathione.” Absorption of glutathione may be better in rats because unlike the gastrointestinal tract of rats, the human gastrointestinal tract contains significant amounts of an **enzyme** (page 506) (**gamma-glutamyltranspeptidase**) that breaks down glutathione.

Preliminary evidence has suggested that absorption of glutathione can occur in the mouth when glutathione tablets are placed between the teeth and the inner cheek.<sup>9</sup>

Some researchers believe that supplements other than oral glutathione may be more effective in raising blood levels of glutathione. For example, in one trial, blood glutathione levels rose nearly 50% in healthy people taking 500 mg of **vitamin C** (page 604) per day for only two weeks.<sup>10</sup> Vitamin C raises glutathione by helping the body manufacture it. In addition to vitamin C, other nutritional compounds that may, according to preliminary research, help increase glutathione levels include **alpha lipoic acid** (page 464),<sup>11</sup> **glutamine** (page 530),<sup>12</sup> **methionine** (page 557),<sup>13</sup> **S-adenosyl methionine (SAMe)** (page 583),<sup>14</sup> and **whey protein** (page 613).<sup>15</sup> **Vitamin B<sub>6</sub>** (page 600), **riboflavin** (page 598), and **selenium** (page 584) are required in the manufacture of glutathione. The extent to which any of these nutrients effectively increases glutathione levels in humans remains unclear.

Studies using intravenous or intramuscular glutathione have found it to be useful for preventing clot formation during operations;<sup>16</sup> reducing the side effects and increasing the efficacy of chemotherapy drugs (particularly cisplatin in women with ovarian cancer);<sup>17, 18</sup> treating **Parkinson's disease** (page 343);<sup>19</sup> reducing blood pressure in people with **diabetes** (page 152) who had **high blood pressure** (page 246);<sup>20</sup> and increasing sperm counts in men with **low sperm counts** (page 305).<sup>21, 22</sup> A glutathione nasal spray has also reduced symptoms in people with chronic **rhinitis** (page 407).<sup>23</sup> Whether oral preparations are also effective is unknown at this time. A small study in eight patients with liver cancer using oral glutathione showed modest benefits in women, but not in men, when given in a daily amount of 5,000 mg.<sup>24</sup>

An unpublished preliminary study of eight colon cancer patients also found that oral glutathione appeared to have **anticancer** (page 87) activity.<sup>25</sup> Nonetheless, because questions exist about the extent to which oral glutathione can be absorbed, some doctors are concerned that oral preparations may be either less effective than other forms or not effective at all.

### Where is it found?

Dietary glutathione is found in fresh and frozen fruits and vegetables, fish, and meat.<sup>26</sup> Asparagus, avocado, and walnuts are particularly rich dietary sources of glutathione.

**Glutathione has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Colon cancer (page 134)

### Who is likely to be deficient?

A deficiency can be the result of diseases that increase the need for glutathione, deficiencies of the **amino acids** (page 465) needed for synthesis, or diseases that inhibit glutathione formation.<sup>27</sup> Examples of some health conditions that are associated with glutathione deficiency include **diabetes** (page 152), **low sperm counts** (page 304), liver disease, **cataracts** (page 101), and **HIV infection** (page 239), respiratory distress syndrome, **cancer** (page 87), and idiopathic pulmonary fibrosis. Cigarette smoking is also associated with low glutathione levels because it increases the rate of utilization of glutathione.

### How much is usually taken?

There is very little evidence that taking glutathione supplements provides any benefit, despite promising evidence about the effects of aerosol, intravenous, and intramuscular glutathione, for people with a wide variety of conditions. People who have a proven glutathione deficiency, which may require administration of glutathione intravenously, intramuscularly, or by aerosol, should be treated by a healthcare professional. All ovarian cancer patients currently taking cisplatin (Platinol) should discuss using intravenous glutathione with a healthcare professional.

### Are there any side effects or interactions?

No side effects or interactions are known with oral administration of glutathione.

## GLYCINE

### What is it?

Glycine is a nonessential **amino acid** (page 465) used by the body to build proteins. It is present in considerable amounts in prostate fluid.

Glycine may play a role in maintaining the health of the prostate, since a study of 45 men with **benign pro-**

**static hyperplasia** (page 58) (BPH) found that 780 mg of glycine per day for two weeks and then 390 mg for the next two and a half months, taken in combination with equal amounts of the amino acids, **alanine** (page 463) and **glutamic acid** (page 529), reduced symptoms of the condition.<sup>1</sup> This effect has been reported by others.<sup>2</sup> Glycine also enhances the activity of chemical messengers (neurotransmitters) in the brain that are involved in memory and cognition.<sup>3</sup>

### Where is it found?

Glycine is found in many foods high in protein, such as fish, meat, beans, and dairy.

**Glycine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Schizophrenia (page 393)
★★☆	Benign prostatic hyperplasia (page 58)

### Who is likely to be deficient?

Few people are glycine deficient, in part because the body makes its own supply of the nonessential **amino acids** (page 465).

### How much is usually taken?

Healthy people do not need to supplement with glycine. A physician should be consulted before supplemental glycine is used for the support of serious health conditions.

### Are there any side effects or interactions?

No clear toxicity has emerged from glycine studies. However, people with kidney or liver disease should not consume high intakes of **amino acids** (page 465) without consulting a healthcare professional.

## GRAPEFRUIT SEED EXTRACT

### What is it?

Grapefruit seed extract (GSE) is a substance extracted from grapefruit seeds.

GSE has been shown to exert significant antibiotic effects in test tube studies.<sup>1, 2</sup> However, one study concluded that these effects were due to the chemical preservatives used to stabilize the grapefruit seed extract rather than to any particular compound found in the extract.<sup>3</sup>

Human research using grapefruit seed extract is very limited. In one study, 25 patients with symptoms associated with **irritable bowel syndrome** (page 280) such as intermittent **diarrhea** (page 163), **constipation** (page 137), **flatulence** (page 137), **bloating** (page 137), and abdominal discomfort were treated with either 2 drops of a 0.5% oral solution of grapefruit seed extract twice daily or 150 mg of encapsulated grapefruit seed extract three times daily.<sup>4</sup> After one month, symptoms had improved in 20% of those taking the liquid, while all of the patients taking capsules noted definite improvement of constipation, flatulence, abdominal discomfort, and night rest. These results need confirmation in double-blind studies.

#### Where is it found?

Grapefruit seed extract is available in liquid concentrate and in capsules and tablets.

**Grapefruit seed extract has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Irritable bowel syndrome (page 280)

#### Who is likely to be deficient?

Grapefruit seed extract is not an essential nutrient and no deficiency states have been reported.

#### How much is usually taken?

The typical recommendation for the liquid concentrate is 10–12 drops in 6–7 ounces of water one to three times daily. For capsules and tablets containing dried grapefruit seed extract, the usual recommendation is 100–200 mg one to three times daily.

#### Are there any side effects or interactions?

No side effects are known. The effects of grapefruit seed extract during **pregnancy** (page 363) and breast-feeding have not been sufficiently evaluated.

## GREEN-LIPPED MUSSEL

#### What is it?

Green-lipped mussel (*Perna canaliculus*) is a New Zealand shellfish, from which an extract has been shown to be useful in the treatment of **rheumatoid arthritis** (RA [page 387]) and **osteoarthritis** (OA [page 328]).

Green-lipped mussel inhibits inflammation in the body. Although inflammation is normal under certain conditions, consistent or excessive inflammation can result in **pain** (page 338) and damage to the body, including the joints. The human body makes several chemical mediators of inflammation. Levels of these chemicals in the body may be higher in people with RA who are experiencing symptoms than in symptom-free people with arthritis.<sup>1</sup> Evidence indicates that controlling the production of inflammatory mediators in the body may help improve conditions such as arthritis, **asthma** (page 32), **psoriasis** (page 379), and **inflammatory bowel disease** (page 269) (including **ulcerative colitis** [page 433] and Crohn's disease), all of which involve elements of inflammation.<sup>2</sup>

Research on green-lipped mussel has focused primarily on OA and RA. Although some studies have failed to demonstrate therapeutic benefit of green-lipped mussel in people with arthritis,<sup>3, 4</sup> the outcomes of other studies have been more positive.<sup>5, 6, 7</sup> In one trial, both freeze-dried powder and lipid extract of green-lipped mussel were effective at reducing symptoms in 70% of people with OA and 76% of people with RA.<sup>8</sup> A similar study of people with either OA or RA showed green-lipped mussel reduced pain in 50% and 67% of the patients, respectively, after three months of supplementation.<sup>9</sup>

In 1986, dried mussel extracts became available that were stabilized with a preservative. The earlier studies that found no beneficial effect of green-lipped mussel on arthritis all used preparations that had not been stabilized, a point that may help explain some of the discrepancies in the research. One recent animal study compared the two forms and found a stabilized lipid extract to be significantly more effective than a nonstabilized extract at inhibiting inflammation.<sup>10</sup> Because both forms are currently available on the market, it may be prudent to check on the form.

Nonsteroidal anti-inflammatories (NSAIDs), such as aspirin and ibuprofen, are often used for inflammatory

conditions. However, most of these medications can produce the unfortunate side effect of stomach irritation, which may lead to stomach **ulcer** (page 349) if taken frequently. One animal study found that green-lipped mussel significantly reduced stomach ulcers resulting from taking NSAIDs.<sup>11</sup>

In a double-blind study of people with asthma, supplementation with a proprietary extract of New Zealand green-lipped mussel (Lyprinol) twice a day for 8 weeks significantly decreased daytime wheezing and improved airflow through the bronchi.<sup>12</sup> Each capsule of Lyprinol contains 50 mg of omega-3 fatty acids.

#### Where is it found?

Green-lipped mussels are found in the oceans off New Zealand. In supplement form, green-lipped mussel is available as a lipid extract or a freeze-dried powder.

**Green-lipped mussel has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Asthma (page 32) (Lyprinol) Osteoarthritis (page 328) Rheumatoid arthritis (page 387)

#### Who is likely to be deficient?

Because green-lipped mussel is not an essential nutrient, deficiencies do not occur.

#### How much is usually taken?

The studies on green-lipped mussel have used 210 mg per day of the lipid extract or 1,050–1,150 mg per day of the freeze-dried powder.

#### Are there any side effects or interactions?

Not all studies have demonstrated side effects; however, members of the Australian Rheumatism Association have reported side effects, such as **stomach upset** (page 260), **gout** (page 208), and skin rashes, occurring in people taking certain New Zealand green-lipped mussel extracts.<sup>13</sup> Another researcher observed nausea, **flatulence** (page 137), and **fluid retention** (page 180) in some of the study participants,<sup>14</sup> and one case of **hepatitis** (page 220) has been reported in association with the use of the freeze-dried powder.<sup>15</sup>

People with shellfish **allergy** (page 14) should consult a doctor before taking green-lipped mussel. Compared to lipid preparations, freeze-dried preparations contain substantially more of the protein fraction responsible for allergic reactions.

## HISTIDINE

#### What is it?

Histidine is called a semi-essential **amino acid** (page 465) (protein building block) because adults generally produce adequate amounts but children may not. Histidine is also a precursor of histamine, a compound released by immune system cells during an **allergic reaction** (page 14).

#### Where is it found?

Dairy, meat and poultry, and fish are good sources of histidine.

#### Who is likely to be deficient?

According to limited research, many people with **rheumatoid arthritis** (page 387) have low levels of histidine. Taking histidine supplements might improve arthritis symptoms in some people.<sup>1</sup>

#### How much is usually taken?

Most people do not need to supplement histidine. Optimal levels for others remain unknown. Human research has used between 1 gram and 8 grams per day.

#### Are there any side effects or interactions?

No side effects have been reported with histidine. However, people with kidney or liver disease should not consume large amounts of **amino acids** (page 465) without consulting a healthcare professional.

## HMB

#### What is it?

HMB (beta hydroxy-beta-methylbutyrate) is a metabolite of the essential **amino acid** (page 465) leucine (one of the **branched-chain amino acids** [page 479]).

As with other amino acid-related substances, HMB appears to play a role in the synthesis of protein—including the protein that builds new muscle tissue.

Animal research suggests that HMB may improve the growth of lean muscle tissue,<sup>1</sup> but only preliminary and limited research in humans supports the potential link between HMB and enhanced muscle building<sup>2</sup> or endurance performance<sup>3</sup> in **athletes** (page 43). One study involving people involved in a regular weight-lifting program found that supplements of 3 grams per day of HMB, compared with no supplements, contributed to greater gains of muscle mass and strength over the seven-week study.<sup>4</sup> However, a double-blind, controlled trial found no effect of 3 grams per day of HMB for four weeks on body composition or exercise performance in 41 weight-training football players.<sup>5, 6</sup>

#### Where is it found?

Small amounts of HMB are present in many foods of animal and plant origin, especially **alfalfa** (page 623) and catfish. The **amino acid** (page 465) leucine is metabolized into a compound called alpha-ketoisocaproate (KIC), which is then turned into HMB by the body. Dietary supplements of HMB are also available.

**HMB has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>High cholesterol</b> (page 223)
★★☆	<b>Athletic performance</b> (page 43) (for improving body composition with strength training in untrained people only) <b>HIV support</b> (page 239) (in combination with <b>glutamine</b> [page 530] and <b>arginine</b> [page 467])

#### Who is likely to be deficient?

HMB is not an essential nutrient. The body creates HMB from leucine, so any diet containing sufficient amounts of leucine (most do) should lead to the adequate production of HMB. Limited evidence indicates that athletes may benefit from supplemental intake of HMB.

#### How much is usually taken?

Most people do not need to use HMB. For those involved in regular exercise who do choose to take this supplement, the research generally uses 3 grams of HMB per day in combination with resistive exercise, such as weight lifting.

#### Are there any side effects or interactions?

No safety issues have been reported in the limited number of studies currently available.

## HYDROXYCITRIC ACID

#### What is it?

(-) -Hydroxycitric acid (HCA) is a compound found in *Garcinia cambogia*, a type of fruit. HCA has a chemical structure similar to that of citric acid (the primary acid in citrus fruits).

Preliminary research in the laboratory and in animal research, suggests that HCA may be a useful **weight loss** (page 446) aid.<sup>1, 2</sup> HCA has been demonstrated in the laboratory (but not yet in trials with people) to reduce the conversion of carbohydrates into stored fat by inhibiting certain **enzyme** (page 506) processes.<sup>3, 4</sup> Animal research indicates that HCA suppresses appetite and induces weight loss.<sup>5, 6, 7, 8</sup> One case report found that eating 1 gram of the fruit containing HCA before each meal resulted in the loss of 1 pound per day.<sup>9</sup>

A double-blind trial that provided either 1,500 mg of HCA or a placebo per day to 135 overweight men and women, who also were on a calorie-restricted diet, found after 12 weeks that the HCA supplementation did not produce a significant change in **weight loss** (page 446).<sup>10</sup> Uncontrolled and/or preliminary evidence from several other human trials suggests the possibility that weight loss might occur;<sup>11</sup> however, none of these studies is as methodologically strong as the negative trial previously mentioned. These less-rigorous studies used a similar calorie-restricted diet and a similar amount of HCA as the negative trial. However, the double-blind study used a high-fiber diet not used in the prior studies. It has been suggested that such a diet might limit absorption of HCA.<sup>12</sup> Future studies that measure blood levels of HCA (to check whether or not the supplement was absorbed) are necessary to resolve this issue. At the present time, the effectiveness of HCA for weight loss remains unclear and unproven.

#### Where is it found?

HCA is found in only a few plants, with one rich source being the rind of a little pumpkin-shaped fruit called *Garcinia cambogia*, which is native to Southeast Asia. This fruit (also called Malabar tamarind) is used as a condiment in dishes such as curry.

**HCA has been used in connection with the following conditions** (refer to it for complete information):

Rating	Health Concerns
★☆☆	Weight loss (page 446)

### Who is likely to be deficient?

Since it is not an essential nutrient, HCA is not associated with a deficiency state.

### How much is usually taken?

Optimal amounts of HCA remain unknown. Although dieters sometimes take 500 mg of HCA three times per day (before each meal), this amount is far below the levels used in animal research (figured on a per-pound body weight basis). The effect of HCA is enhanced when used in conjunction with a low-fat diet, because HCA does nothing to reduce the caloric effects of dietary fat. Since HCA's mechanism of action seems to be at least partially a blockade of conversion of simple sugars into fats,<sup>13</sup> it is likely to work best in conjunction with a high simple sugar diet. HCA may therefore be less useful if it only offsets the negative effects of an otherwise unhealthy diet. High-fiber diets may impair absorption of HCA as noted above. HCA supplements are available in many forms, including tablets, capsules, powders, snack bars, and chewing gum.

### Are there any side effects or interactions?

HCA has not been linked to any adverse effects.

## INDOLE-3-CARBINOL

### What is it?

Indole-3-carbinol is one of the major **anticancer** (page 87) substances found in cruciferous (cabbage family) vegetables. It is a member of the class of sulfur-containing chemicals called glucosinolates.<sup>1</sup> It is formed from parent compounds whenever cruciferous vegetables are crushed or cooked.<sup>2,3</sup>

Indole-3-carbinol and other glucosinolates (e.g., other indoles and isothiocyanates such as **sulforaphane** [page 589]) are **antioxidants** (page 467) and potent stimulators of natural detoxifying **enzymes** (page 506) in the body.<sup>4,5</sup> Indole-3-carbinol and other glucosinolates are believed to be responsible for the lowered risk

of cancer in humans that is associated with the consumption of broccoli and other cruciferous vegetables like cauliflower, cabbage, and kale.<sup>6,7,8,9,10,11,12</sup>

Feeding indole-3-carbinol or broccoli extracts rich in indole-3-carbinol has dramatically reduced the frequency, size, and number of tumors in laboratory rats exposed to a carcinogen. It appears to be especially protective against **breast** (page 65)<sup>13,14,15,16</sup> and **cervical**<sup>17,18</sup> cancers because of a number of actions, including an ability to increase the breakdown of estrogen. However, while most animal studies report protective effects, a few indicate that indole-3-carbinol may actually promote cancer formation in certain situations, depending upon the chemical initiator of cancer, method of exposure, and species of animal studied.<sup>19,20</sup>

Until there is further research and more human clinical data to determine if indole-3-carbinol actually inhibits rather than stimulates cancer formation, some researchers have recommended proceeding with caution when using isolated indole-3-carbinol as a dietary supplement.<sup>21</sup> The areas where its use has currently been documented in humans are only preliminary, but the results are promising. Indole-3-carbinol reduced or halted the formation of precancerous lesions (papillomas) in 12 out of 18 people with recurrent respiratory tract papillomas.<sup>22</sup> In addition, in a small double-blind trial, supplementation with 200 or 400 mg of indole-3-carbinol per day for 12 weeks reversed early-stage cervical cancer in 8 of 17 women.<sup>23</sup> Preliminary studies have also shown indole-3-carbinol has significantly increased the conversion of estrogen from cancer-producing forms to nontoxic breakdown products.<sup>24,25</sup>

### Where is it found?

Indole-3-carbinol is found in highest concentrations in broccoli, but is also found in other cruciferous vegetables, such as cauliflower, cabbage, and kale.

**Indole-3-carbinol has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Cancer prevention (page 87) (cervical cancer)

### Who is likely to be deficient?

As indole-3-carbinol is not an essential nutrient, no deficiency state exists.

### How much is usually taken?

Based upon preliminary studies it is estimated that the minimum amount required for the prevention of **breast cancer** (page 65) is 300 to 400 mg daily.<sup>26</sup>

### Are there any side effects or interactions?

No side effects from indole-3-carbinol have been reported.

## INOSINE

### What is it?

Inosine is a nucleoside, one of the basic compounds comprising cells. It is a precursor to **adenosine** (page 461), an important energy molecule, and plays many supportive roles in the body.

Based upon anecdotal reports by Russian and Eastern European athletes, inosine has been investigated for exercise-boosting (ergogenic) effects. However, controlled studies have concluded that inosine does not improve **athletic performance** (page 43) and may even impair it.<sup>1,2</sup>

Inosine is a precursor to uric acid, a compound that occurs naturally in the body. Uric acid is believed to block the effect of a toxic free-radical compound (peroxynitrite) that may play a role in the development of multiple sclerosis (MS).<sup>3</sup> In an attempt to raise uric acid levels, ten patients with MS were treated with inosine in amounts up to 3 grams per day for 46 weeks. Three of the ten treated patients showed some evidence of improved function and the others remained stable.<sup>4</sup> Controlled studies are needed to confirm these preliminary results.

### Where is it found?

Inosine is found in **brewer's yeast** (page 480) and organ meats. It is also available as a supplement.

**Inosine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Multiple Sclerosis</b> (page 323)

### Who is likely to be deficient?

Inosine is not an essential nutrient, so deficiencies do not occur.

### How much is usually taken?

Although a common amount of inosine taken by athletes is 5,000–6,000 mg per day, little scientific evidence supports the use of this supplement in any amount.

### Are there any side effects or interactions?

No side effects have been reported with the use of inosine for two to five days in the limited research available. However, unused inosine is converted by the body to uric acid, which may be hazardous to people at risk for **gout** (page 208).

## INOSITOL

### What is it?

Inositol is part of the **vitamin B-complex** (page 603). It is required for proper formation of cell membranes.

Inositol affects nerve transmission and helps in transporting fats within the body. Inositol differs from inositol hexaniacinate, a form of **vitamin B<sub>3</sub>** (page 598).

### Where is it found?

Nuts, beans, wheat and wheat bran, cantaloupe, and oranges are excellent sources of inositol. Most dietary inositol is in the form of phytate.

**Inositol has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Anxiety</b> (page 30) <b>Depression</b> (page 145) Obsessive-compulsive disorder
★☆☆	<b>Bipolar disorder/manic depression</b> (page 61) <b>Diabetes</b> (page 152)

### Who is likely to be deficient?

Clear deficiency of inositol has not been reported, although people with **diabetes** (page 152) have increased excretion and may benefit from inositol supplementation.

### How much is usually taken?

Most people do not need to take inositol. In addition, the small amounts commonly found in **multivitamin**

**supplements** (page 559) are probably unnecessary and ineffective. Doctors sometimes suggest 500 mg twice per day. For **depression** (page 145), **anxiety** (page 30), and obsessive-compulsive disorder, 12–18 grams per day has been shown to be effective in double-blind trials.<sup>1, 2, 3, 4</sup>

#### Are there any side effects or interactions?

Toxicity has not been reported, although people with chronic renal failure show elevated levels and should not take inositol, except under medical supervision.

Large amounts of phytate, the common dietary form of inositol, reduce the absorption of **calcium** (page 483), **iron** (page 540), and **zinc** (page 614). However, supplemental inositol does not have this effect.

One review article suggested that inositol may stimulate uterine contractions.<sup>5</sup> While no research has demonstrated that inositol actually has this effect, women who are or could become **pregnant** (page 363) should consult a doctor before taking inositol.

## IODINE

#### What is it?

Iodine is a trace mineral needed to make thyroid hormones, which are necessary for maintaining normal metabolism in all cells of the body.

Reports suggest that iodine may have a number of other important functions in the body unrelated to thyroid function that might help people with a wide variety of conditions.<sup>1</sup> These other uses for iodine are only supported by minimal research.

#### Where is it found?

Seafood, iodized salt, and sea vegetables—for example, **kelp** (page 543)—are high in iodine. Processed food may contain added iodized salt. Iodine is frequently found in dairy products. Vegetables grown in iodine-rich soil also contain this mineral.

#### Iodine has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Childhood intelligence in newborns (if deficient) <b>Goiter</b> (page 206) (iodine deficiency-induced)
★★☆	<b>Hypothyroidism</b> (page 252)
★☆☆	<b>Fibrocystic breast disease</b> (page 189)

#### Who is likely to be deficient?

People who avoid dairy, seafood, processed food, and iodized salt can become deficient. Iodine deficiency can cause **low thyroid function** (page 252), **goiter** (page 206), and cretinism. Although iodine deficiencies are now uncommon in Western societies, the U.S. population has shown a trend of significantly decreasing iodine intake from 1988–1994.<sup>2</sup> If this trend continues, iodine deficiency diseases may become more common.

#### How much is usually taken?

Since the introduction of iodized salt, iodine supplements are unnecessary and not recommended for most people. For strict vegetarians who avoid salt and sea vegetables, 150 mcg per day is commonly supplemented. This amount is adequate to prevent a deficiency and higher amounts are not necessary.

#### Are there any side effects or interactions?

High amounts (several milligrams per day) of iodine can interfere with normal thyroid function and should not be taken without consulting a doctor.<sup>3</sup> Although potassium iodide supplementation (prescribed for some skin disorders) is usually well-tolerated, it has been known to produce adverse reactions such as rashes, itching or lesions on the skin, gastrointestinal symptoms, or **hypothyroidism** (page 252), especially in people with a prior history of thyroid problems.<sup>4</sup> Because of such potential problems, the use of potassium iodide therapy should be supervised by a doctor. The average diet provides about four times the recommended amount of iodine. For susceptible people, that amount of iodine may be enough to cause health problems.<sup>5</sup> A possible link to thyroid **cancer** (page 87) has been observed in areas where an iodine-rich diet is consumed,<sup>6, 7</sup> and among populations that supplement with iodine.<sup>8, 9</sup> However, there is insufficient evidence to conclude that iodine supplementation is responsible for the increased incidence of thyroid cancer. Some people react to supplemental iodine, the first symptom of which is usually an acne-like rash.

When people with small, nontoxic goiter (living in areas not deficient in iodine) received iodine injections, they had a higher incidence of abnormal antibodies suggestive of the early stages of autoimmune thyroid disease.<sup>10</sup>

Children with iodine deficiency may also have **iron-deficiency anemia** (page 278), and this anemia may interfere with the therapeutic action of iodine supplementation.<sup>11</sup> Correcting iron deficiency in such chil-

dren with iron supplements has been shown to improve the efficacy of oral iodine in treating goiter.<sup>12</sup>

## IP-6

### What is it?

IP-6 is a naturally occurring component of plant fiber.

IP-6 may possess **antioxidant** (page 467),<sup>1</sup> **anticancer** (page 87),<sup>2</sup> and other beneficial properties. For example, animal studies have shown that supplementation with large amounts of IP-6 provides substantial protection against **colon cancer** (page 123)<sup>3</sup> and possibly **breast cancer** (page 65).<sup>4,5</sup> In one of these studies, the effect of pure IP-6 was significant, while an equivalent amount given as a wheat-bran breakfast cereal was not.<sup>6</sup> However, while some animals are able to digest and/or absorb IP-6, it is not known whether humans can.<sup>7</sup> This uncertainty limits the applicability of the animal research to humans, except possibly for colon cancer prevention, which may not depend on absorption. Unfortunately, human research to date has not found an association between higher levels of dietary IP-6 in the colon and reduced indicators of colon cancer risk.<sup>8</sup> Injections of IP-6 used to treat cancerous tumors in mice have been shown to cause partial regression of these tumors.<sup>9</sup>

IP-6 may have a beneficial effect on blood sugar control, similar to the effect of many dietary fibers.<sup>10</sup> However, no studies have been done to test this effect on people with blood sugar disorders.

### Where is it found?

IP-6, also known as phytate, is associated with dietary **fiber** (page 512) and thus is naturally present in a wide variety of plant foods, especially wheat bran, whole grains, and legumes. Usual dietary intakes range from 1–1.5 grams phytate per day.

**IP-6 has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Kidney stones (page 284)

### Who is likely to be deficient?

While there is no dietary requirement for IP-6, people consuming diets low in dietary **fiber** (page 512) and nuts and seeds have the lowest intake.

### How much is usually taken?

Virtually all research suggesting beneficial effects from taking IP-6 involve animals and not people. It is not known whether IP-6 would be useful for humans or if so, what would be the optimal amount.

### Are there any side effects or interactions?

Phytate in foods has been associated with reduced mineral absorption.<sup>11</sup> In particular, significant interference with **iron** (page 540) absorption has been reported.<sup>12</sup> People who are **iron deficient** (page 278) should talk with a doctor before supplementing with IP-6. Even for those who are not iron deficient, if IP-6 supplements are taken for more than several months and fatigue—a possible symptom of iron deficiency develops, a doctor should be consulted. How much iron supplementation (if any) should be used to counteract the iron-depleting effect of IP-6 varies from person to person, though many people are likely to not require such supplementation.

## IPIFLAVONE

### What is it?

Ipriflavone is a synthetic **flavonoid** (page 516) (iso-flavone) derived from the **soy** (page 587) compound daidzein.

Ipriflavone promotes the incorporation of **calcium** (page 483) into bone. It also inhibits bone breakdown. Many clinical studies, including numerous double-blind studies, have clearly shown that long-term treatment with ipriflavone (along with 1,000 mg supplemental calcium per day) is both safe and effective in halting bone loss in **postmenopausal** (page 311) women or in women who have had their ovaries removed. Ipriflavone has also been found to improve bone density in cases of **osteoporosis** (page 333).<sup>1, 2, 3, 4, 5, 6</sup>

In one study demonstrating that ipriflavone prevents bone loss, 56 recently post-menopausal women with low bone density were assigned to receive either ipriflavone (200 mg three times per day) or a placebo for two years.<sup>7</sup> Consistent with most other studies with ipriflavone, all women also received 1,000 mg of elemental calcium daily. While vertebral (spine) bone density declined by 4.9% after two years in women taking only calcium, there was no change in bone density among women taking ipriflavone supplementation.

Double-blind studies in women with osteoporosis

have also shown positive effects. The most significant studies were performed in elderly women with a history of vertebral fractures due to osteoporosis.<sup>8, 9, 10</sup> Ipriflavone therapy not only stopped bone loss, it actually increased bone density and significantly eliminated or improved vertebral fractures and bone **pain** (page 338).

One double-blind study has failed to confirm the beneficial effect of ipriflavone. In that study, ipriflavone was no more effective than a placebo for preventing bone loss in postmenopausal women with osteoporosis.<sup>11</sup> The women in this negative study were older (average age, 63.3 years) than those in most other ipriflavone studies and had relatively severe osteoporosis. It is possible that ipriflavone works only in younger women or in those with less severe osteoporosis.

### Where is it found?

Ipriflavone does occur naturally in food but only in trace amounts. It is available as a nutritional supplement.

### Ipriflavone has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Osteoporosis (page 333)

### Who is likely to be deficient?

As ipriflavone is not an essential nutrient, no deficiency state exists.

### How much is usually taken?

The typical supplemental amount of ipriflavone is 200 mg three times daily. Taking 300 mg twice daily has been reported to be just as effective as 200 mg three times per day.<sup>12</sup>

### Are there any side effects or interactions?

In a trial of ipriflavone for osteoporosis, 29 of the 132 women in the ipriflavone group completing the three-year trial developed a clinically significant drop in lymphocytes.<sup>13</sup> These cells, which make up approximately 22 to 28% of the white blood cells in the normal adult, are critical components of the immune system and its ability to respond to viral infections. In some of these women, a return to normal levels took almost two years after they had stopped the ipriflavone. Since this finding has been reported in one other smaller clinical

trial,<sup>14</sup> it suggests that women choosing to take ipriflavone should have their lymphocytes measured regularly by their doctor.

In double-blind studies, the frequency of perceived side effects in ipriflavone-treated people (14.5%) was actually less than that observed in people receiving the placebo (16.1%).<sup>15</sup> Side effects were mainly mild **stomach upset** (page 260). Researchers recommend that patients with severe kidney disease take a lower amount of ipriflavone (200 to 400 mg daily).<sup>16</sup>

## IRON

### What is it?

Iron is an essential mineral. It is part of hemoglobin, the oxygen-carrying component of the blood. **Iron-deficient** (page 278) people tire easily in part because their bodies are starved for oxygen. Iron is also part of myoglobin, which helps muscle cells store oxygen. Without enough iron, adenosine triphosphate (ATP; the fuel the body runs on) cannot be properly synthesized. As a result, some iron-deficient people become fatigued even when their hemoglobin levels are normal (i.e., when they are not anemic).

Although iron is part of the **antioxidant enzyme** (page 467) catalase, iron is not generally considered an antioxidant, because too much iron can cause oxidative damage.

### Where is it found?

The most absorbable form of iron, called "heme" iron, is found in oysters, meat and poultry, and fish. Non-heme iron is also found in these foods, as well as in dried fruit, molasses, leafy green vegetables, wine, and iron supplements. Acidic foods (such as tomato sauce) cooked in an iron pan can also be a source of dietary iron.

### Iron has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Childhood intelligence (for deficiency) <b>Depression</b> (page 145) (for deficiency) <b>Iron-deficiency anemia</b> (page 278) <b>Menorrhagia</b> (page 314) (heavy menstruation) (for treatment of iron-deficiency only)

Rating	Health Concerns
★★☆	<b>Athletic performance</b> (page 43) (for treatment of iron-deficiency only) <b>Attention deficit-hyperactivity disorder</b> (page 55) (for deficiency only) <b>Breast-feeding support</b> (page 74) <b>Canker sores</b> (page 90) <b>Celiac disease</b> (page 102) (for treatment of iron-deficiency only) <b>Pre- and post-surgery health</b> (page 357) (if deficient or for major surgery) <b>Pregnancy and postpartum support</b> (page 363) (with medical supervision) <b>Restless legs syndrome</b> (page 384) (only if iron-deficiency)
★☆☆	<b>Alzheimer's disease</b> (page 19) (in combination with <b>coenzyme Q<sub>10</sub></b> [page 496] and <b>vitamin B<sub>6</sub></b> [page 600]) <b>Dermatitis herpetiformis</b> (page 151) <b>HIV support</b> (page 239) <b>Infertility (female)</b> (page 187) (for treatment of iron-deficiency only)

### Who is likely to be deficient?

Vegetarians eat less iron than non-vegetarians, and the iron they eat is somewhat less absorbable. As a result, vegetarians are more likely to have reduced iron stores.<sup>1</sup> However, **iron deficiency** (page 278) is not usually caused by a lack of iron in the diet alone. An underlying cause, such as iron loss in menstrual blood, often exists.

**Pregnant** (page 363) women, **marathon runners** (page 43), people who take aspirin, and those who have **parasitic** (page 343) infections, **hemorrhoids** (page 219), **ulcers** (page 349), **ulcerative colitis** (page 433), **Crohn's disease** (page 141), gastrointestinal **cancers** (page 87), or other conditions that cause blood loss or **malabsorption** (page 304) are likely to become deficient.

Infants living in inner city areas may be at increased risk of **iron-deficiency anemia** (page 278)<sup>2</sup> and suffer more often from developmental delays as a result.<sup>3, 4</sup> Supplementation of infant formula with iron up to 18 months of age in inner city infants has been shown to prevent iron-deficiency anemia and to reduce the decline in mental development seen in such infants in some,<sup>5</sup> but not all,<sup>6</sup> studies.

Breath-holding spells are a common problem affecting about 27% of healthy children.<sup>7</sup> These spells have been associated with iron-deficiency anemia,<sup>8</sup> and several studies have reported improvement of breath-holding spells with iron supplementation.<sup>9, 10, 11, 12</sup>

People who fit into one of these groups, even **pregnant** (page 363) women, shouldn't automatically take iron supplements. Fatigue, the first symptom of iron deficiency, can be caused by many other things. A doctor should assess the need for iron supplements, since taking iron when it isn't needed does no good and may do some harm.

### Which forms of supplemental iron are best?

All iron supplements are not the same. Ferrous iron (e.g. ferrous sulfate) is much better absorbed than ferric iron (e.g. ferric citrate).<sup>13, 14</sup> The most common form of iron supplement is ferrous sulfate, but it is known to produce intestinal side effects (such as **constipation** [page 137], nausea, and **bloating** [page 137]) in many users.<sup>15</sup> Some forms of ferrous sulfate are enteric-coated to delay tablet dissolving and prevent some side effects,<sup>16</sup> but enteric-coated iron may not absorb as well as iron from standard supplements.<sup>17, 18, 19</sup> Other forms of iron supplements, such as ferrous fumarate,<sup>20, 21</sup> ferrous gluconate,<sup>22</sup> heme iron concentrate,<sup>23, 24, 25, 26</sup> and iron glycine **amino acid** (page 465) chelate<sup>27, 28</sup> are readily absorbed and less likely to cause intestinal side effects.

### How much is usually taken?

If a doctor diagnoses **iron deficiency** (page 278), iron supplementation is essential. To treat iron deficiency, a common recommended amount for an adult is 100 mg per day; that amount is usually reduced after the deficiency is corrected. When iron deficiency is diagnosed, the doctor must also determine the cause. Usually it's not serious (such as normal menstrual blood loss or blood donation). Occasionally, however, iron deficiency signals **ulcers** (page 349) or even **colon cancer** (page 123).

Some **premenopausal** (page 311) women become marginally iron deficient unless they supplement with iron. However, the 18 mg of iron present in many **multivitamin-mineral supplements** (page 559) is often adequate to prevent deficiency. A doctor should be consulted to determine the amount of iron that is needed.

### Are there any side effects or interactions?

Iron (ferrous sulfate) is the leading cause of accidental poisonings in children.<sup>29, 30, 31</sup> The incidence of iron poisonings in young children increased dramatically in 1986. Many of these children obtained the iron from a child-resistant container opened by themselves or another child, or left open or improperly closed by an adult.<sup>32</sup> Deaths in children have occurred from ingesting as little as 200 mg to as much as 5.85 grams of

iron.<sup>33</sup> Keep iron-containing supplements out of a child's reach.

Hemochromatosis, hemosiderosis, polycythemia, and iron-loading anemias (such as thalassemia and **sickle cell anemia** [page 403]) are conditions involving excessive storage of iron. Supplementing iron can be quite dangerous for people with these diseases.

Supplemental amounts required to overcome iron deficiency can cause **constipation** (page 137). Sometimes switching the form of iron (see "Which forms of supplemental iron are best?" above), getting more exercise, or treating the constipation with **fiber** (page 512) and fluids is helpful, though fiber can reduce iron absorption (see below). Sometimes the amount of iron must be reduced if constipation occurs.

Some researchers have linked excess iron levels to **diabetes** (page 152),<sup>34</sup> **cancer** (page 87),<sup>35</sup> increased risk of **infection** (page 265),<sup>36</sup> **systemic lupus erythematosus** (page 421) (SLE),<sup>37</sup> exacerbation of **rheumatoid arthritis** (page 387),<sup>38</sup> and Huntington's disease.<sup>39</sup> The greatest concern has surrounded the possibility that excess storage of iron in the body increases the risk of **heart disease** (page 98).<sup>40, 41, 42</sup> Two analyses of published studies came to different conclusions about whether iron could increase heart disease risk.<sup>43, 44</sup> One trial has suggested that such a link may exist, but only in some people (possibly smokers or those with elevated **cholesterol** (page 223) levels).<sup>45</sup> The link between excess iron and any of the diseases mentioned earlier in this paragraph has not been definitively proven. Nonetheless, too much iron causes **free radical damage** (page 467), which can, in theory, promote or exacerbate most of these diseases. People who are not iron deficient should generally not take iron supplements.

Patients on kidney dialysis who are given injections of iron frequently experience "oxidative stress". This is because iron is a pro-oxidant, meaning that it interacts with oxygen molecules in ways that can damage tissues. These adverse effects of iron therapy may be counteracted by supplementation with **vitamin E** (page 609).<sup>46</sup>

Supplementation with iron, or iron and zinc, has been found to improve **vitamin A** (page 595) status among children at high risk for deficiency of the three nutrients.<sup>47</sup>

People with **hepatitis C** (page 220) who have failed to respond to interferon therapy have been found to have higher amounts of iron within the liver. Moreover, reduction of iron levels by drawing blood has been shown to decrease liver injury caused by hepatitis C.<sup>48</sup> Therefore, people with hepatitis C should avoid iron supplements.

In some people, particularly those with **diabetes**

(page 152), **insulin resistance syndrome** (page 273), or liver disease, a genetic susceptibility to iron overload has been reported.<sup>49</sup>

Many foods, beverages, and supplements have been shown to affect the absorption of iron.<sup>50</sup>

Foods, beverages and supplements that interfere with iron absorption include

- **Green tea's** (page 686) (*Camellia sinensis*)<sup>51, 52, 53, 54</sup> effect may be desirable for people with iron overload diseases, such as hemochromatosis; the inhibitory effect of green tea on iron absorption was 26% in one study<sup>55</sup>
- Coffee (*Coffea arabica, C. robusta*)<sup>56, 57, 58</sup>
- Red wine, particularly the polyphenol component (also found in tea),<sup>59, 60</sup> since wine is also a dietary source of iron, it is not clear whether drinking red wine would lead to a deficiency of iron
- Phytate (phytic acid), found in unleavened wheat products such as matzoh, pita, and some rye crackers; in wheat germ, **oats** (page 716), nuts, cacao powder, vanilla extract, beans, and many other foods, and in **IP-6** (page 539) supplements<sup>61, 62, 63</sup>
- Whole wheat bran, independent of its phytate content, has been shown to inhibit iron absorption<sup>64</sup>
- **Calcium** (page 483) from food and supplements interferes with heme-iron absorption<sup>65, 66</sup>
- Soy protein<sup>67, 68</sup>
- Eggs<sup>69, 70</sup>

Foods and supplements that increase iron absorption include

- Meat, poultry, and fish<sup>71, 72, 73, 74, 75</sup>

Although **vitamin C** (page 604) increases iron absorption,<sup>76, 77, 78, 79</sup> the effect is relatively minor.<sup>80</sup>

Taking **vitamin A** (page 595) with iron helps treat **iron deficiency** (page 278), since vitamin A improves the absorption and/or utilization of iron.<sup>81, 82</sup>

Although soy protein has been shown to decrease iron absorption (see above), certain soy-containing foods (e.g. tofu, miso, tempeh) have significantly improved iron absorption.<sup>83</sup> Some soy sauces may also enhance iron absorption.<sup>84</sup>

Alcohol, but not red wine, has been reported to increase the absorption of ferric, but not ferrous, iron.<sup>85, 86</sup>

Iron has been reported to potentially interfere with **manganese** (page 553) absorption. In one trial, women with high iron status had relatively poor absorption of manganese.<sup>87</sup> In another trial studying manganese/iron

interactions in women, increased intake of “non-heme iron”—the kind of iron found in most supplements—decreased manganese status.<sup>88</sup> These interactions suggest that taking **multiminerals** (page 559) that include manganese may protect against manganese deficiencies that might otherwise be triggered by taking isolated iron supplements.

## KELP

### What is it?

Kelp is a sea vegetable that is a concentrated source of minerals, including **iodine** (page 538), **potassium** (page 572), **magnesium** (page 551), **calcium** (page 483), and **iron** (page 540). Kelp as a source of iodine assists in making thyroid hormones, which are necessary for maintaining normal metabolism in all cells of the body.

### Where is it found?

Kelp can be one of several brown-colored seaweed species called *Laminaria*.

**Kelp has been used in connection with the following condition** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Iodine deficiency

### Who is likely to be deficient?

People who avoid sea vegetables, as well as dairy, seafood, processed food, and the salt shaker, can become deficient in iodine. Iodine deficiency can cause **low thyroid function** (page 252), **goiter** (page 206), and cretinism. Although iodine deficiency is now uncommon in Western societies, the U.S. population has shown a trend of significantly decreasing iodine intake.

### How much is usually taken?

Since the introduction of iodized salt, additional sources of **iodine** (page 538), such as kelp, are not necessary for most people. However, kelp can be consumed as a source of other minerals. A report from Great Britain indicated that the average kelp-based supplement contained 1,000 mcg of iodine (the adult RDA in the United States is 150 mcg per day). It has been suggested that intakes above 2,000 mcg per day should be regarded as excessive or potentially harmful.<sup>1</sup>

### Are there any side effects or interactions?

There have been several case reports of high intakes of kelp providing too much **iodine** (page 538) and interfering with normal thyroid function.<sup>2, 3, 4, 5, 6</sup> People with thyroid disease should check with a doctor before taking supplements that contain kelp.

## L-CARNITINE

### What is it?

L-carnitine is made in the body from the **amino acids** (page 465) **lysine** (page 550) and **methionine** (page 557), and is needed to release energy from fat. It transports fatty acids into mitochondria, the powerhouses of cells. In infancy, and in situations of high energy needs, such as **pregnancy** (page 363) and breast-feeding, the need for L-carnitine can exceed production by the body. Therefore, L-carnitine is considered a “conditionally essential” nutrient.<sup>1</sup>

L-carnitine’s actions appear to be particularly important in the heart. As an example, patients with **diabetes** (page 152) and **high blood pressure** (page 246) were given 4 grams of L-carnitine per day in a preliminary study.<sup>2</sup> After 45 weeks, **irregular heartbeat** (page 93) and abnormal heart functioning decreased significantly compared with nonsupplemented patients. For **congestive heart failure** (page 134), much of the research has used a modified form of carnitine called propionyl-L-carnitine (PC). In one double-blind trial, using 500 mg PC per day led to a 26% increase in exercise capacity after six months.<sup>3</sup> In other research, patients with congestive heart failure given 1.5 grams PC daily for 15 days had a 21% increase in exercise tolerance and a 45% increase in oxygen consumption.<sup>4</sup>

Research shows that people who supplement with L-carnitine while engaging in an exercise regimen are less likely to experience muscle soreness.<sup>5</sup> However, the belief that carnitine’s effect on energy release will help build muscle or improve **athletic performance** (page 43) has, so far, not been supported by most research.<sup>6, 7</sup> In a double-blind study of trained athletes, supplementation with 2 grams of L-carnitine two hours before and after a 20 km run failed to improve physical performance or exercise recovery.<sup>8</sup>

L-carnitine has been given to people with chronic lung disease in trials investigating how the body responds to exercise, however.<sup>9, 10</sup> In these double-blind reports, 2 grams of L-carnitine taken twice per day for

two to four weeks led to positive changes in lung function and metabolism during exercise.

Beta thalassemia major is an inherited, fatal form of anemia commonly seen in people of Mediterranean descent. People with beta thalassemia major invariably require blood transfusions, which can eventually result in **iron** (page 540) overload.<sup>11</sup> L-carnitine stabilizes red blood cells and supplementation may decrease the need for blood transfusions. In a preliminary study, children with beta thalassemia major who took 100 mg of L-carnitine per 2.2 pounds of body weight per day for three months had a significantly decreased need for blood transfusions.<sup>12</sup>

### Where is it found?

Dairy and red meat contain the greatest amounts of carnitine. Therefore, people who have a limited intake of meat and dairy products tend to have lower L-carnitine intakes.

**L-carnitine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Angina</b> (page 27) <b>Congestive heart failure</b> (page 134) (propionyl-L-carnitine) <b>Heart attack</b> (page 212) <b>Intermittent claudication</b> (page 276) (propionyl-L-carnitine)
★★☆	<b>Anemia</b> (page 25) (for thalassemia) <b>Attention deficit-hyperactivity disorder</b> (page 55) <b>Chronic fatigue syndrome</b> (page 111) <b>Chronic obstructive pulmonary disease</b> (page 114) (COPD) <b>Diabetes</b> (page 152) <b>High triglycerides</b> (page 235) <b>Infertility (male)</b> (page 305) <b>Intermittent claudication</b> (page 276) (L-carnitine) <b>Sprains and strains</b> (page 412) (for preventing exercise-related muscle injury)
★☆☆	<b>Athletic performance</b> (page 43) (for ultra-endurance only) Beta thalassemia major <b>Cardiomyopathy</b> (page 95) (only for children with inherited cardiomyopathy) Chemotherapy-induced fatigue <b>High cholesterol</b> (page 223) <b>Liver cirrhosis</b> (page 290) <b>Mitral valve prolapse</b> (page 319) <b>Raynaud's disease</b> (page 382) <b>Weight loss</b> (page 446)

### Who is likely to be deficient?

Carnitine deficiencies are rare, even in strict vegetarians, because the body produces carnitine relatively easily.

Rare genetic diseases can cause a carnitine deficiency. Also, deficiencies are occasionally associated with other diseases, such as **diabetes** (page 152) and **cirrhosis** (page 290).<sup>13, 14</sup> Among people with diabetes, carnitine deficiency is more likely to be found in persons experiencing complications of diabetes (such as **retinopathy** (page 385), hyperlipidemia, or neuropathy), suggesting that carnitine deficiency may play a role in the development of these complications.<sup>15</sup> A carnitine deficiency can also result from oxygen deprivation which can occur in some **heart conditions** (page 98). In Italy, L-carnitine is prescribed for **heart failure** (page 134), **heart arrhythmias** (page 93), **angina** (page 27), and lack of oxygen to the heart.<sup>16</sup>

### How much is usually taken?

Most people do not need carnitine supplements. For therapeutic use, typical amounts are 1–3 grams per day.

It remains unclear whether the propionyl-L-carnitine form of carnitine used in **congestive heart failure** (page 134) research has greater benefits than the L-carnitine form, since limited research in both animals and humans with the more common L-carnitine has also shown very promising effects.<sup>17</sup>

### Are there any side effects or interactions?

L-carnitine has not been consistently linked with any toxicity.

The body needs **lysine** (page 550), **methionine** (page 557), **vitamin C** (page 604), **iron** (page 540), **niacin** (page 598), and **vitamin B<sub>6</sub>** (page 600) to produce carnitine.

## L-TYROSINE

### What is it?

L-tyrosine is a nonessential **amino acid** (page 465) (protein building block) that the body synthesizes from **phenylalanine** (page 568), another amino acid. Tyrosine is important to the structure of almost all proteins in the body. It is also the precursor of several neurotransmitters, including L-dopa, dopamine, norepinephrine, and epinephrine.

L-tyrosine, through its effect on neurotransmitters, may affect several health conditions, including **Parkin-**

**son's disease** (page 345), **depression** (page 145), and other mood disorders. Studies have suggested that tyrosine may help people with depression.<sup>1</sup> Preliminary findings indicate a beneficial effect of tyrosine, along with other amino acids, in people affected by dementia, including **Alzheimer's disease** (page 19).<sup>2</sup> Due to its role as a precursor to norepinephrine and epinephrine (two of the body's main stress-related hormones) tyrosine may also ease the adverse effects of environmental, psychosocial, and physical stress.<sup>3, 4, 5, 6, 7, 8, 9</sup>

L-tyrosine is converted by skin cells into melanin, the dark pigment that protects against the harmful effects of ultraviolet light. Thyroid hormones, which have a role in almost every process in the body, also contain tyrosine as part of their structure.

People born with the genetic condition **phenylketonuria** (page 354) (PKU) are unable to metabolize the amino acid **phenylalanine** (page 568). Mental retardation and other severe disabilities can result. While dietary phenylalanine restriction prevents these problems, it also leads to low tyrosine levels in many (but not all) people with PKU. Tyrosine supplementation may be beneficial in some people with PKU, though the evidence is conflicting.<sup>10</sup>

#### Where is it found?

Dairy products, meats, fish, wheat, **oats** (page 716), and most other protein-containing foods contain tyrosine.

#### L-tyrosine has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Depression</b> (page 145) <b>Phenylketonuria</b> (page 354) (for deficiency)
★☆☆	<b>Alcohol withdrawal support</b> (page 12) <b>Parkinson's disease</b> (page 345)

#### Who is likely to be deficient?

Some people affected by **PKU** (page 354) are deficient in tyrosine. Tyrosine levels are occasionally low in **depressed** (page 145) people.<sup>11</sup> Any person losing large amounts of protein, such as those with some kidney diseases, may be deficient in several **amino acids** (page 465), including tyrosine.<sup>12</sup>

#### How much is usually taken?

Most people should not supplement with L-tyrosine. Some human research with people suffering from a va-

riety of conditions used 100 mg per 2.2 pounds of body weight, equivalent to about 7 grams per day for an average-sized person. The appropriate amount to use in people with **PKU** (page 354) is not known, therefore, the monitoring of blood levels by a physician is recommended.

#### Are there any side effects or interactions?

L-tyrosine has not been reported to cause any serious side effects. However, it is not known whether long-term use of L-tyrosine, particularly in large amounts (such as more than 1,000 mg per day) is safe. For that reason, long-term use of L-tyrosine should be monitored by a doctor.

**Vitamin B<sub>6</sub>** (page 600), **folic acid** (page 520), and **copper** (page 499) are necessary for conversion of L-tyrosine into neurotransmitters.

## LACTASE

### Lactase

#### What is it?

Lactase is the enzyme in the small intestine that digests lactose (the naturally occurring sugar in milk).

A few children and many people after childhood do not produce sufficient lactase, resulting in impaired ability to digest milk. These people are **lactose intolerant** (page 288) and often suffer from symptoms including cramps, gas, and **diarrhea** (page 163). Lactose intolerance is best diagnosed by a doctor. However, a reasonably reliable home test for lactose intolerance is to drink two 8-ounce glasses of milk on an empty stomach and note any gastrointestinal symptoms that develop over the next four hours; repeat the test on another day using several ounces of cheese (which does not contain much lactose). If symptoms result from milk but not cheese, then the person probably has lactose intolerance. If symptoms occur with both milk and cheese, the person may be **allergic** (page 14) to dairy.

#### Where is it found?

Lactase is produced by the body. Dairy products have varying levels of lactose, which affects how much lactase is required for proper digestion. Milk, ice cream, and yogurt contain significant amounts of lactose—although for complex reasons yogurt often doesn't trigger symptoms in lactose-intolerant people.

**Lactase has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Diarrhea</b> (page 163) (for lactose-intolerant people) <b>Indigestion and heartburn</b> (page 260) (for lactose-intolerant people) <b>Irritable bowel syndrome</b> (page 280) (for lactose-intolerant people) <b>Lactose intolerance</b> (page 288)

#### Who is likely to be deficient?

Only one-third of all people retain the ability to digest lactose into adulthood. Most individuals of Asian, African, and Native American descent are **lactose intolerant** (page 288). In addition, half of Hispanics and about 20 percent of Caucasians do not produce lactase as adults.<sup>1</sup>

#### How much is usually taken?

Lactose-reduced milk is available and can be used in the same quantities as regular milk. Lactase drops can be added to regular milk 24 hours before drinking to reduce lactose levels. Lactase drops, capsules, and tablets can also be taken directly, as needed, immediately before a meal that includes lactose-containing dairy products. The degree of lactose intolerance varies by individual, so a greater or lesser amount of lactase may be needed to eliminate symptoms of lactose intolerance.

#### Are there any side effects or interactions?

Lactase is safe and does not produce side effects.

Some, but not all, studies suggest that lactose-intolerant individuals absorb less **calcium** (page 483).<sup>2</sup>

## LECITHIN/PHOSPHATIDYL CHOLINE

#### What is it?

When medical researchers use the term “lecithin,” they are referring to a purified substance called phosphatidyl choline (PC) that belongs to a special category of fat-soluble substances called phospholipids.

Phospholipids are essential components of cell membranes. Supplements labeled as “lecithin” usually contain 10–20% PC. Relatively pure PC supplements are generally labeled as “phosphatidylcholine.” PC best duplicates supplements used in medical research.

Choline by itself (without the “phosphatidyl” group) is also available in foods and supplements. In high amounts, however, pure choline can make people smell like fish, so it’s rarely used, except in the small amounts found in **multivitamin supplements** (page 559).

#### What does it do?

PC acts as a supplier of choline, which is needed for cell membrane integrity and to facilitate the movement of fats in and out of cells. It is also a component of the neurotransmitter acetylcholine and is needed for normal brain functioning, particularly in infants. Although the human body can synthesize choline, additional amounts from the diet are considered essential under certain circumstances. For this reason, PC has been used in a number of preliminary studies for a wide variety of neurological and psychiatric disorders, though not every study suggests that supplemental choline is capable of reaching the brain.<sup>1</sup> Choline participates in many functions involving cellular components called phospholipids.

#### Where is it found?

Choline, the major constituent of PC, is found in soybeans, liver, oatmeal, cabbage, and cauliflower. Soybeans, egg yolks, meat, and some vegetables contain PC. Lecithin (containing 10–20% PC) is added to many processed foods in small amounts for the purpose of maintaining texture consistency.

**Phosphatidyl choline has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>High homocysteine</b> (page 235) <b>Liver cirrhosis</b> (page 290) <b>Neural tube defects</b> (page 63) (prevention) <b>Tardive dyskinesia</b> (page 425)
★☆☆	<b>Alzheimer's disease</b> (page 19) <b>Bipolar disorder</b> (page 61) <b>Gallbladder attacks</b> (page 193) <b>Hepatitis</b> (page 220) <b>High cholesterol</b> (page 223)

**Who is likely to be deficient?**

Although choline deficiencies have been artificially induced in people, little is known about human deficiency in the real world.

**How much is usually taken?**

Small amounts of choline are present in many **B-complex** (page 603) and **multivitamin** (page 559) supplements.

**Are there any side effects or interactions?**

With several grams of choline per day, some people will experience abdominal discomfort, **diarrhea** (page 163), or nausea. Supplementing choline in large amounts (over 1,000 mg per day) can lead to a fishy body odor. PC does not have this effect. **Depression** (page 145) has been reported as a side effect in people taking large amounts of choline, such as 9 grams per day.

The body uses both PC and **pantothenic acid** (page 568) to form acetylcholine.

## LIPASE

**What is it?**

Lipase is an **enzyme** (page 506) that is used by the body to break down dietary fats into an absorbable form.

When lipase levels are insufficient to break down dietary fats, greasy, light-colored stools ensue; this condition is called steatorrhea.

**Where is it found?**

Most of the body's lipase is manufactured in the pancreas, although some of it is secreted in the saliva, as well. Pancreatin contains lipase along with two other groups of **enzymes** (page 506): proteases and amylase.

**Lipase has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Cystic fibrosis</b> (page 143)
★★☆	<b>Indigestion</b> (page 260) (for pancreatic insufficiency only)
★☆☆	<b>Celiac disease</b> (page 102) <b>Crohn's disease</b> (page 141)

**Who is likely to be deficient?**

People with pancreatic insufficiency and **cystic fibrosis** (page 143) frequently require supplemental lipase and other enzymes. In addition, those with **celiac disease** (page 102)<sup>1</sup> or **Crohn's disease** (page 141)<sup>2</sup> and perhaps some people suffering from **indigestion** (page 260)<sup>3</sup> may be deficient in **pancreatic enzymes** (page 506) including lipase.

**How much is usually taken?**

Products that contain lipase also usually contain other **enzymes** (page 506) that help digest carbohydrates and protein. In the U.S., pancreatin, which contains lipase, amylase, and proteases, is rated against a government standard. For example, "9X pancreatin" is nine times stronger than the government standard. Each "X" contains 25 USP units of amylase, 2 USP units of lipase, and 25 USP units of proteolytic enzymes. Taking 1.5 grams of 9X pancreatin (or a higher amount at lower potencies) with each meal can help people with pancreatic insufficiency digest food.

**Are there any side effects or interactions?**

Lipase does not generally cause any side effects at the amounts listed above.

## LIVER EXTRACTS

**What are they?**

Extracts of beef (bovine) liver are a rich natural source of many **vitamins and minerals** (page 559), including **iron** (page 540).

Liver extracts provide the most absorbable form of iron—heme iron—and other nutrients critical in building blood, including **vitamin B<sub>12</sub>** (page 601) and **folic acid** (page 520). Liver extracts can contain as much as 3–4 mg of heme iron per gram. In addition to its use as a source of iron, liver extracts are also used by some healthcare practitioners to support liver function and boost energy levels. Liver extracts have been tested in people with chronic liver disease. However, no clear benefit has been demonstrated.<sup>1, 2</sup>

**Where are they found?**

Liver extracts are available as nutritional supplements in capsules and tablets.

**Liver extracts have been used in connection with the following conditions** (refer to it for complete information):

Rating	Health Concerns
★★★	Iron-deficiency anemia (page 278)

#### Who is likely to be deficient?

As it is not an essential nutrient, no deficiency state exists.

#### How much is usually taken?

The recommended amount depends on the concentration, method of preparation, and quality of the liver extract.

#### Are there any side effects or interactions?

No side effects or adverse reactions have been reported. Liver extracts should not be used by people suffering from iron-storage disorders, such as hemochromatosis.

As the liver is a major filtering organ for many potentially toxic environmental chemicals, some doctors are concerned that consumption of liver extracts may result in increased intake of these chemicals.

## LUTEIN

#### What is it?

Lutein is an **antioxidant** (page 467) in the **carotenoid** (page 488) family (a group of naturally occurring fat-soluble pigments found in plants). Lutein is the primary carotenoid present in the central area of the retina called the macula.

Lutein may act as a filter to protect the macula from potentially damaging forms of light. Consequently, lutein appears to be associated with protection from age-related **macular degeneration** (page 303) (the leading cause of blindness in older adults).

#### Where is it found?

Spinach, kale, collard greens, romaine lettuce, leeks, peas, and egg yolks are good sources of lutein.

**Lutein has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Macular degeneration (page 303) Cataracts (page 101)

#### Who is likely to be deficient?

While a deficiency has not been identified, people who eat more lutein-containing foods appear to be at lower risk of **macular degeneration** (page 303). One study found that adults with the highest dietary intake of lutein had a 57% decreased risk of macular degeneration compared with those people with the lowest intake, and of the **carotenoids** (page 488), lutein and zeaxanthin are most strongly associated with this protection.<sup>1</sup> In a preliminary study, a similar link was suggested between low dietary lutein and increased risk of **cataracts** (page 101).<sup>2</sup>

#### How much is usually taken?

People showing protection from **macular degeneration** (page 303) have been reported to have eaten about 6 mg of lutein per day from food. Lutein, in supplemental form, should be taken with fat-containing food to improve absorption.<sup>3</sup>

#### Are there any side effects or interactions?

No adverse effects from lutein have been reported.

Lutein functions together with zeaxanthin, another **antioxidant** (page 467) found in the same foods and supplements as lutein.

## LYCOPENE

#### What is it?

Lycopene, found primarily in tomatoes, is a member of the **carotenoid** (page 488) family—which includes **beta-carotene** (page 469) and similar compounds found naturally in food—and has potent **antioxidant** (page 467) capabilities.

A study conducted by Harvard researchers examined the relationship between carotenoids and the risk of prostate **cancer** (page 87).<sup>1</sup> Of the carotenoids studied,

only lycopene was clearly linked to protection. The men who had the greatest amounts of lycopene in their diet (6.5 mg per day or more) showed a 21% decreased risk of **prostate cancer** (page 371) compared with those eating the least. This report suggests that lycopene may be an important tool in the prevention of prostate cancer. This study also reported that those who ate more than ten servings per week of tomato-based foods had a 35% decreased risk of prostate cancer compared with those eating less than 1.5 weekly servings. When the researchers looked at only advanced prostate cancer, the high lycopene eaters had an 86% decreased risk (although this did not reach statistical significance due to the small number of cases).

Contrary to popular opinion, research suggests that there is no preferential concentration of lycopene in prostate tissue.<sup>2</sup> Although prostate cancer patients have been reported to have low levels of lycopene in the blood,<sup>3</sup> and lycopene appears to be a potent inhibitor of **human cancer** (page 87) cells in test-tubes,<sup>4</sup> evidence is conflicting concerning whether an increased intake of tomato products is protective against prostate cancer. Some studies, like the one discussed above, have reported that high consumption of tomatoes and tomato products reduces risk of prostate cancer.<sup>5,6</sup> Other studies, however, are inconclusive,<sup>7</sup> and some have found no protective association.<sup>8,9,10,11,12</sup>

There is some evidence that lycopene may be helpful in the treatment of prostate cancer. In a preliminary trial, 26 men with prostate cancer were randomly assigned to receive lycopene (15 mg twice a day) or no lycopene for three weeks before undergoing prostate surgery. Prostate tissue was then obtained during surgery and examined. Compared with the unsupplemented men, those receiving lycopene were found to have significantly less aggressive growth of cancer cells.<sup>13</sup> In addition, a case report has been published of a 62-year-old man with advanced prostate cancer who experienced a regression of his tumor after starting 10 mg of lycopene per day and 300 mg of **saw palmetto** (page 743) three times per day. As saw palmetto has not been previously associated with improvements in prostate cancer, the authors of the report attributed the response to the lycopene.<sup>14</sup> Long-term controlled studies are needed to confirm these promising initial reports.

There is no evidence that tomato intake has any effect on **benign prostatic hyperplasia** (page 58) (BPH).

Another study found that for the 25% of people with the greatest tomato intake, the risk for cancers of the gastrointestinal tract was 30–60% lower, compared with those who ate fewer tomatoes. These reduced risks were statistically significant.<sup>15</sup> A study of women found that the 75% who ate the least amount of tomatoes had between 3.5 and 4.7 times the risk for pre-cancerous changes of the cervix (cervical intraepithelial neoplasia).<sup>16</sup> Other researchers have also reported evidence suggesting that high dietary lycopene may be linked to protection from **cervical dysplasia** (page 3).<sup>17</sup> While preliminary evidence also links dietary lycopene with protection from **breast cancer** (page 65),<sup>18</sup> another study did not find this link.<sup>19</sup>

In a review of 72 studies,<sup>20</sup> one researcher reported 57 associations between tomato intake or blood lycopene levels and decreased risk of cancer. Of these associations, 35 were statistically significant. The benefit was strongest for prostate, **lung** (page 298), and stomach cancers, although protective associations were also found for cancers of the pancreas, **colon** (page 134), rectum, esophagus, oral cavity, breast, and cervix. Because the data were from observational studies, a cause-and-effect relationship cannot be firmly established. However, the consistently lower risk of cancer associated with higher consumption of lycopene-containing tomatoes, provides a strong foundation for further research on lycopene.

In Europe, researchers have found a statistically significant association between high dietary lycopene and a 48% lower risk of **heart disease** (page 98).<sup>21</sup> Lycopene supplementation has also boosted **immune function** (page 255) in the elderly. In that trial, 15 mg of lycopene per day increased natural killer cell activity by 28% in 12 weeks.<sup>22</sup>

### Where is it found?

Tomatoes and tomato-containing foods are high in lycopene. In the Harvard study, the only tomato-based food that did not correlate with protection was tomato juice. In an unblinded, controlled trial, lycopene supplementation, but not tomato juice, effectively increased the body's lycopene stores.<sup>23</sup> These studies suggest that the lycopene present in tomato juice is poorly absorbed. However, other research indicates that significant amounts of lycopene from tomato juice can, in fact, be absorbed.<sup>24</sup> Other foods that contain lycopene include watermelon, pink grapefruit, and guava.

**Lycopene has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Asthma</b> (page 32), exercise-induced <b>Preeclampsia</b> (page 361) <b>Prostate cancer</b> (page 371)
★☆☆	<b>Atherosclerosis</b> (page 38) (prevention only) <b>Cancer risk reduction</b> (page 87) <b>Immune function</b> (page 255) <b>Macular degeneration</b> (page 303)

#### Who is likely to be deficient?

This is unknown, but people who do not eat diets high in tomatoes or tomato products are likely to consume less than optimal amounts.

#### How much is usually taken?

The ideal intake of lycopene is currently unknown; however, the men in the Harvard study with the greatest protection against **cancer** (page 87) consumed at least 6.5 mg per day.

#### Are there any side effects or interactions?

No adverse effects have been reported with the use of lycopene.

#### Where is it found?

**Brewer's yeast** (page 480), legumes, dairy, fish, and meat all contain significant amounts of lysine.

**Lysine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Cold sores</b> (page 119) (recurrence prevention)
★★☆	<b>Genital Herpes</b> (page 200)
★☆☆	<b>Shingles</b> (page 401)

#### Who is likely to be deficient?

Most people, including vegans (vegetarians who also avoid dairy and eggs), consume adequate amounts of lysine. However, vegans whose diets contain large amounts of grains and only minimal amounts of beans could become deficient in lysine. **Athletes** (page 43) involved in frequent vigorous exercise have increased need for essential **amino acids** (page 465), although most diets meet these increased needs. The essential amino acid requirements of **burn** (page 85) patients may exceed the amount of lysine in the diet.

#### How much is usually taken?

Most people do not require lysine supplementation. Doctors often suggest that people with recurrent **herpes simplex** (page 119) infections take 1,000–3,000 mg of lysine per day.

## LYSINE

#### What is it?

Lysine is an essential **amino acid** (page 465) needed for growth and to help maintain nitrogen balance in the body. (Essential amino acids cannot be made in the body and must be supplied by the diet or **supplements** [page 559].)

Lysine appears to help the body absorb and conserve **calcium** (page 483).<sup>1</sup> Lysine has many functions in the body because it is incorporated into many proteins, which are used by the body for a variety of purposes. Lysine interferes with replication of **herpes viruses** (page 200) and is therefore often prescribed by doctors to people with **cold sores** (page 119) or genital herpes. A review of the research trials investigating the effects of lysine on people with cold sores shows that most, though not all, trials support the use of lysine.<sup>2</sup>

#### Are there any side effects or interactions?

In animals, high amounts of lysine have been linked to increased risk of **gallstones** (page 193)<sup>3</sup> and **elevated cholesterol** (page 223).<sup>4</sup> At supplemental amounts, no consistent problems have been reported in humans, though abdominal cramps and transient **diarrhea** (page 163) have occasionally been reported at very high (15–40 grams per day) intakes.<sup>5</sup>

Lysine supplementation increases the absorption of **calcium** (page 483) and may reduce its excretion.<sup>6</sup> As a result, some researchers believe that lysine may eventually be shown to have a role in the prevention and treatment of **osteoporosis** (page 333).<sup>7</sup>

Lysine works with other essential **amino acids** (page 465) to maintain growth, lean body mass, and the body's store of nitrogen.

## MAGNESIUM

### What is it?

Magnesium is an essential mineral to the human body. It is needed for bone, protein, and fatty acid formation, making new cells, activating **B vitamins** (page 603), relaxing muscles, clotting blood, and forming adenosine triphosphate (ATP; the energy the body runs on). The secretion and action of insulin also require magnesium.

Magnesium also acts in a way related to **calcium** (page 483) channel blocker drugs. This effect may be responsible for the fact that under certain circumstances magnesium has been found to potentially improve vision in people with glaucoma.<sup>1</sup> Similarly, this action might account for magnesium's ability to **lower blood pressure** (page 246).<sup>2</sup>

Since magnesium has so many different actions in the body, the exact reasons for some of its clinical effects are difficult to determine. For example, magnesium has reduced hyperactivity in children in preliminary research.<sup>3</sup> Other research suggests that some children with attention deficit-hyperactivity disorder (ADHD) have lowered levels of magnesium. In a preliminary but controlled trial, 50 ADHD children with low magnesium (as determined by red blood cell, hair, and serum levels of magnesium) were given 200 mg of magnesium per day for six months.<sup>4</sup> Compared with 25 other magnesium-deficient ADHD children, those given magnesium supplementation had a significant decrease in hyperactive behavior.

Magnesium levels have been reported to be low in those with **chronic fatigue syndrome** (page 111) (CFS),<sup>5</sup> and magnesium injections have been reported to improve symptoms.<sup>6</sup> Oral magnesium supplementation has also improved symptoms in those people with CFS who had low magnesium levels in another report, although magnesium injections were sometimes necessary.<sup>7</sup> However, other research reports no evidence of magnesium deficiency in people with CFS.<sup>8,9</sup> The reason for this discrepancy remains unclear. People with CFS considering magnesium supplementation should have their magnesium status checked beforehand by a doctor. Only people with magnesium deficiency appear to benefit from this therapy.

People with **diabetes** (page 152) tend to have lower magnesium levels compared with those who have normal glucose tolerance.<sup>10</sup> Supplementation with magnesium overcomes this problem<sup>11</sup> and may help some diabetics improve glucose tolerance.

Magnesium may be beneficial for bladder problems in women, especially common disturbances in bladder control and the sense of "urgency." A double-blind trial found that women who took 350 mg of magnesium hydroxide (providing 147 mg elemental magnesium) twice daily for four weeks had better bladder control and fewer symptoms than women who took a placebo.<sup>12</sup>

Magnesium supplementation may reduce dehydration of red blood cells in **sickle cell anemia** (page 403) patients. Administration of 540 mg per day of magnesium pidolate to sickle cell anemia patients was seen after six months, to reverse some of the characteristic red blood cell abnormalities and to dramatically reduce the number of painful days for these patients.<sup>13</sup> This preliminary trial was not blinded, so placebo effect could not be ruled out. Magnesium pidolate is also an unusual form of magnesium. It is unknown whether other forms of magnesium would produce similar results.

### Where is it found?

Nuts and grains are good sources of magnesium. Beans, dark green vegetables, fish, and meat also contain significant amounts.

**Magnesium has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Cardiac arrhythmia</b> (page 93) <b>Congestive heart failure</b> (page 134) <b>Diabetes</b> (page 152) <b>Dysmenorrhea</b> (page 171) <b>Gestational hypertension</b> (page 202) <b>Kidney stones</b> (page 284) (citrate in combination with <b>potassium</b> (page 572) citrate) <b>Migraine headaches</b> (page 314) <b>Mitral valve prolapse</b> (page 319)

### Who is likely to be deficient?

Magnesium deficiency is common in people taking “potassium (page 572)-depleting” prescription diuretics. Taking too many laxatives can also lead to deficiency. **Alcoholism** (page 12), severe **burns** (page 85), **diabetes** (page 152), and **heart failure** (page 134) are other potential causes of deficiency. In a study of urban African-American people (predominantly female), the overall prevalence of magnesium deficiency was 20%. People with a history of alcoholism were six times more likely to have magnesium deficiency than were people without such a history.<sup>14</sup> The low magnesium status seen in alcoholics with **liver cirrhosis** (page 290) contributes to the development of **hypertension** (page 246) in these people.<sup>15</sup>

Almost two-thirds of people in intensive care hospital units have been found to be magnesium deficient.<sup>16</sup> Deficiency may also occur in people with chronic **diarrhea** (page 163), pancreatitis, and other conditions associated with **malabsorption** (page 304).

Fatigue, **abnormal heart rhythms** (page 93), muscle weakness and spasm, **depression** (page 145), loss of appetite, listlessness, and **potassium** (page 572) depletion can all result from a magnesium deficiency. People with these symptoms should be evaluated by a doctor before taking magnesium supplements.

As previously mentioned, magnesium levels have been found to be low in people with **chronic fatigue syndrome** (page 111).

Deficiencies of magnesium that are serious enough to cause symptoms should be treated by medical doctors, as they might require intravenous administration of magnesium.<sup>17</sup>

### How much is usually taken?

Most people don’t consume enough magnesium in their diets. Many nutritionally oriented doctors recommend 250–350 mg per day of supplemental magnesium for adults.

### Are there any side effects or interactions?

Comments in this section are limited to effects from taking oral magnesium. Side effects from intravenous use of magnesium are not discussed.

Taking too much magnesium often leads to **diarrhea** (page 163). For some people this can happen with amounts as low as 350–500 mg per day. More serious problems can develop with excessive magnesium intake from magnesium-containing laxatives. However, the amounts of magnesium found in nutritional supplements are unlikely to cause such problems. People with kidney disease should not take magnesium supplements without consulting a doctor.

**Vitamin B<sub>6</sub>** (page 600) increases the amount of magnesium that can enter cells. As a result, these two nutrients are often taken together. Magnesium may compete for absorption with other minerals, particularly **calcium** (page 483). Taking a **multimineral supplement** (page 559) avoids this potential problem.

## MALIC ACID

### What is it?

Malic acid is a naturally occurring compound that plays a role in the complex process of deriving adenosine triphosphate (ATP; the energy currency that runs the body) from food.

Although uncontrolled research had suggested that the combination of 1,200–2,400 mg per day of malic acid and 300–600 mg of **magnesium** (page 551) for eight weeks reduced symptoms of **fibromyalgia** (page

191),<sup>1</sup> double-blind evidence has shown that malic acid plus magnesium fails to help people with this condition.<sup>2</sup>

#### Where is it found?

Malic acid is found in a wide variety of fruits and vegetables, but the richest source is apples, which is why malic acid is sometimes referred to as “apple acid.”

**Malic acid has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Fibromyalgia (page 191)

#### Who is likely to be deficient?

A deficiency in humans is unlikely, since the body can produce malic acid.

#### How much is usually taken?

Healthy people do not need to take malic acid as a supplement. Research has been conducted with 1,200–2,400 mg of malic acid in combination with 300–600 mg of elemental **magnesium** (page 551).

#### Are there any side effects or interactions?

Current research does not indicate any adverse effects from the use of malic acid in moderate amounts.

## MANGANESE

#### What is it?

Manganese is an essential trace mineral needed for healthy skin, bone, and cartilage formation, as well as glucose tolerance. It also helps activate superoxide dismutase (SOD)—an important **antioxidant enzyme** (page 467).

#### Where is it found?

Nuts and seeds, wheat germ, wheat bran, leafy green vegetables, beet tops, tea, and pineapple are all good sources of manganese.

**Manganese has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Tardive dyskinesia (page 425)
★☆☆	Diabetes (page 152)
	Hypoglycemia (page 251)
	Osgood-Schlatter disease (page 327)
	Osteoporosis (page 333)
	Sprains and strains (page 412)

#### Who is likely to be deficient?

Many people consume less than the 2–5 mg of manganese currently considered safe and adequate. Nonetheless, clear deficiencies are rare. People with **osteoporosis** (page 333) sometimes have low blood levels of manganese, suggestive of deficiency.<sup>1</sup>

#### How much is usually taken?

Whether most people would benefit from manganese supplementation remains unclear. While there is no recommended dietary allowance, the National Research Council’s “estimated safe and adequate daily dietary intake” is 2–5 mg.<sup>2</sup> The Institute of Medicine recommends that intake of manganese from food, water and dietary supplements should not exceed the tolerable daily upper limit of 11 mg per day. In contrast, the 5–15 mg often found in high-potency **multivitamin-mineral supplements** (page 559) is generally considered to be a reasonable level by many doctors, though many manufacturers are likely to reformulate their products to contain no more than 11 mg per daily amount.

#### Are there any side effects or interactions?

Amounts found in supplements (5–20 mg) have not been linked with any toxicity. Excessive intake of manganese rarely lead to psychiatric symptoms. However, most reports of manganese toxicity in otherwise healthy people have been in those people who chronically inhaled manganese dust at their jobs e.g., miners or alloy plant workers. Other sources of manganese intoxication are now recognized, including total parenteral nutrition (TPN) in patients who are being fed intravenously<sup>3, 4, 5</sup> and pesticides containing manganese in agricultural workers who have been exposed.<sup>6</sup>

Preliminary research suggests that people with cir-

**rrosis** (page 290)<sup>7</sup> or cholestasis (blocked bile flow from the gall bladder)<sup>8</sup> may not be able to properly excrete manganese. Until more is known, these people should not supplement manganese. Manganese supplementation (3–5 mg per day) has caused severe **hypoglycemia** (page 251) (low blood sugar) in a person with insulin-dependent **diabetes** (page 152).<sup>9</sup> People with diabetes who want to take manganese should consult their doctor.

Several minerals, such as **calcium** (page 483) and **iron** (page 540), and possibly **zinc** (page 614), reduce the absorption of manganese.<sup>10</sup> Of these interactions, the link to iron may be the most important. In one study, women with high iron status had relatively poor absorption of manganese.<sup>11</sup> In another report of manganese/iron interactions in women, increased intake of “non-heme iron”—the kind of iron found in most supplements—decreased manganese status.<sup>12</sup> These interactions suggest that taking multi-minerals that include manganese may protect against manganese deficiencies that might otherwise be triggered by taking isolated mineral supplements, particularly iron.

ested in its use, especially during prolonged endurance exercise.<sup>7</sup> However, no effect on carbohydrate sparing or endurance exercise performance has been shown, with moderate amounts of MCT (30–45 grams).<sup>8,9</sup> Trials using very large amounts (about 85 grams) have produced conflicting results. One study found increased performance when MCT was added to a 10% carbohydrate solution,<sup>10</sup> and another study actually reported decreased performance, probably due to gastrointestinal distress, in athletes using MCT.<sup>11</sup>

Because some short-term studies have shown that MCT lowers blood glucose levels, a group of researchers investigated the use of MCT to treat people with type 2 (adult onset or non-insulin-dependent) **diabetes** (page 152) mellitus.<sup>12</sup> In nonhospitalized people with diabetes who consumed MCT for an average of 17.5% of their total calorie intake for 30 days, MCT did not improve diabetic control by most measures.<sup>13</sup>

### Where are they found?

Medium chain triglycerides are found in coconut oil, palm kernel oil, and butter. MCT are also available as a supplement.

**Medium chain triglycerides have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Athletic performance</b> (page 43) <b>Diabetes</b> (page 152)

### Who is likely to be deficient?

Most people consume adequate amounts of fat in their diets and many people consume excessive amounts, so extra fat intake as medium chain triglycerides is unnecessary.

### How much is usually taken?

The best amount of medium chain triglycerides to take is currently unknown. Athletes are not likely to benefit from less than 50 grams during **exercise** (page 43). Larger amounts may possibly help some, but may also impair performance if not combined with carbohydrate.

### Are there any side effects or interactions?

Consuming medium chain triglycerides on an empty stomach can lead to **gastrointestinal upset** (page 260). Anyone with **cirrhosis** (page 290) or other liver prob-

## MEDIUM CHAIN TRIGLYCERIDES

### What are they?

Medium-chain triglycerides (MCT) are a class of fatty acids. Their chemical composition is of a shorter length than the long-chain fatty acids present in most other fats and oils, which accounts for their name. They are also different from other fats in that they have a slightly lower calorie content<sup>1</sup> and they are more rapidly absorbed and burned as energy, resembling carbohydrate more than fat.<sup>2</sup>

MCT have been shown to increase calorie burning compared with other fats.<sup>3,4</sup> However, researchers estimate that half of the calories in the diet would have to be eaten as MCT for significant **weight loss** (page 446) to occur.<sup>5</sup> Obese women on a calorie-restricted diet using MCT for 24% of total calories, experienced no greater weight loss after three months, than when regular fat was used.<sup>6</sup> Whether MCT would help people lose weight on a normal diet has not been adequately studied.

Since MCT is more rapidly used for energy than other fats, some **athletes** (page 43) have been inter-

lems should check with a doctor before using MCT. Two reports suggest that MCT may raise serum **cholesterol** (page 223) and/or **triglycerides** (page 235).<sup>14, 15</sup> MCT is actually the preferred fatty acid source for cirrhotic patients, but only when used intermittently.<sup>16</sup>

## MELATONIN

### What is it?

Melatonin is a natural hormone that regulates the human biological clock.

Double-blind research with young adults has shown that melatonin facilitates **sleep** (page 270).<sup>1</sup> Another study of healthy, young adults reported that melatonin significantly shortened the time needed to go to sleep, reduced the number of night awakenings, and improved sleep quality.<sup>2</sup> Other researchers reported the time needed to get to sleep was reduced with melatonin.<sup>3</sup>

Melatonin is also helpful in relieving symptoms of **jet lag** (page 283). One double-blind trial, involving a sample of international flight crew members taking either melatonin or a placebo for three days before and five days after an international flight, found that melatonin significantly reduced symptoms of jet lag and resulted in a quicker recovery of preflight energy levels and alertness.<sup>4</sup>

Less than 1 mg of melatonin has lowered pressure within the eyes of healthy people,<sup>5</sup> but studies have not yet been published on the effects of using melatonin with people who have **glaucoma** (page 205).

Melatonin might help some people suffering from **depression** (page 145). A small double-blind study suggested that supplementation with small amounts of melatonin (0.125 mg taken twice per day) may reduce **winter depression** (page 397).<sup>6</sup> People with major depressive disorders sometimes have sleep disturbances. Melatonin has been shown to be effective at improving the quality of sleep of people with major depression.<sup>7</sup> However, because of the possibility that melatonin could exacerbate depression, it should only be used for this purpose, under a doctor's supervision.

When some people take melatonin to treat sleep disorders, chronic **tension headaches** (page 428) are relieved.<sup>8</sup> Melatonin has also relieved **cluster headaches** (page 117) in double-blind research.<sup>9</sup> Some researchers have suggested that melatonin's role in regulating core body temperature may be responsible for preventing

cluster headaches,<sup>10</sup> which have been reported to be triggered by increased body heat.<sup>11</sup>

Melatonin also regulates **immunity** (page 255). One group of doctors reported two successfully treated cases of sarcoidosis that it attributed to melatonin's immune-modulating effect.<sup>12</sup> Also, because of its effects on the immune system, melatonin has been given to people with **cancer** (page 87) in many research trials. Low blood levels of melatonin are associated with an increased risk of uterine cancer.<sup>13</sup> Melatonin has significantly reduced the level of prostate specific antigen (PSA, a marker for cancer) in **prostate cancer** (page 371) patients.<sup>14</sup> Melatonin inhibits **breast cancer** (page 65) cells in test tubes<sup>15</sup> and has put some women with breast cancer into remission in preliminary research.<sup>16</sup> Melatonin supplementation has improved disease-free survival in people with melanoma<sup>17</sup> and increased survival in people with brain cancer<sup>18</sup> and **lung cancer** (page 298).<sup>19</sup> Melatonin exerts anti-inflammatory activity that may be responsible for its anticancer properties.<sup>20</sup>

In a double-blind trial, people who had difficulty sleeping as a result of **tinnitus** (page 430) were better able to sleep if given 3 mg melatonin per night for one month rather than a placebo.<sup>21</sup> Although melatonin did not reduce overall symptom scores for tinnitus, people in this trial with higher symptom scores did appear to obtain some benefit.

Melatonin supplementation may be helpful in treating **epilepsy** (page 183); 5–10 mg of melatonin taken at bedtime reduced the frequency of seizures and improved sleep in a group of children with epilepsy in a small, preliminary trial.<sup>22</sup> However, in a group of children suffering from neurological disorders, 1–5 mg of melatonin per night led to an increase in the rate of seizures.<sup>23</sup> Children with a seizure disorder called "myoclonus" were reported to have been cured by supplementing with 3–5 mg of melatonin per day in a preliminary trial.<sup>24</sup> Until more is known, children with neurological conditions should take melatonin only under medical supervision.

Melatonin may be useful in the treatment of **fibromyalgia** (page 191). In a small, uncontrolled preliminary study, 3 mg of melatonin at bedtime was found to reduce tender points associated with this disorder. **Pain** (page 338) and fatigue improved only slightly.<sup>25</sup>

Children with Angelman's syndrome (a rare, genetic disorder characterized by severe mental retardation, seizures, and sleep disturbances) may benefit from low

amounts of melatonin. In an uncontrolled study, children with Angelman's Syndrome who took 0.3 mg of melatonin one-half to one hour before bedtime had significant improvement in nighttime sleep patterns and a reduction in movement disturbances during sleep.<sup>26</sup>

Animal studies indicate that melatonin secretion may regulate cardiovascular activity,<sup>27, 28</sup> blood pressure,<sup>29</sup> and blood flow to the brain.<sup>30</sup> In healthy young men, oral administration of 1 mg of melatonin significantly reduced blood pressure and levels of stress hormones within 90 minutes.<sup>31</sup> To date, no clinical trials in humans have tested the efficacy of melatonin for **hypertension** (page 246).

### Where is it found?

Melatonin is produced by the pineal gland, located within the brain. Levels of melatonin in the body fluctuate with the cycles of night and day. The highest melatonin levels are found at night. Melatonin is present in foods only in trace amounts.

### Melatonin has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Angelman's syndrome (sleep disturbances only) <b>Cluster headaches</b> (page 117) <b>Colon cancer</b> (page 123) <b>Depression</b> (page 145) <b>Insomnia</b> (page 270) <b>Jet lag</b> (page 283) <b>Schizophrenia</b> (page 393) (for sleep disturbances only) <b>Tardive dyskinesia</b> (page 425) <b>Tinnitus</b> (page 430) ( <b>insomnia</b> [page 270]-associated)
★★★	<b>Age-related cognitive decline</b> (page 8) <b>Breast cancer</b> (page 65) <b>Epilepsy</b> (page 183) <b>Fibromyalgia</b> (page 191) <b>Glaucoma</b> (page 205) <b>Lung cancer</b> (page 298) <b>Migraine headaches</b> (page 316) <b>Myoclonus</b> <b>Prostate cancer</b> (page 371) <b>Sarcoidosis</b>

### Who is likely to be deficient?

Although elderly people often have difficulty sleeping<sup>32</sup> and melatonin supplements have been shown to im-

prove sleep in the elderly,<sup>33</sup> melatonin secretion does not appear to decline in healthy older adults to a significant degree, despite many preliminary reports to the contrary.<sup>34</sup> Most of these preliminary studies failed to verify that older subjects were healthy and not using drugs that suppress melatonin secretion (e.g., aspirin, ibuprofen, beta-blockers). Routine replacement of melatonin in elderly persons is, therefore, not recommended.

Adults with **insomnia** (page 270) have been shown to have lower melatonin levels.<sup>35</sup> Frequent travelers and shift workers are also likely to benefit from melatonin for the resynchronization of their sleep schedules,<sup>36</sup> though a melatonin "deficiency" as such does not exist for these people. Patients with **heart disease** (page 98) have been reported to have low melatonin levels, but whether this abnormality increases the risk of heart disease or whether heart disease leads to the low melatonin level is not yet known.<sup>37</sup> People with **schizophrenia** (page 393) were found to have low melatonin output and experienced significantly improved sleep following melatonin replacement supplementation.<sup>38</sup>

### How much is usually taken?

Normally, the body secretes melatonin for several hours per night—an effect best duplicated with time-release supplements. Studies using timed-release melatonin for **insomnia** (page 270) have reported good results.<sup>39</sup> Many doctors suggest 1–3 mg of melatonin taken one to two hours before bedtime. Studies with people suffering from sarcoidosis or **cancer** (page 87) have used very high amounts of melatonin—typically 20 mg per night. Such levels should never be taken without the supervision of a doctor. Melatonin should not be taken during the day.

### Are there any side effects or interactions?

Melatonin is associated with few side effects. However, morning grogginess, undesired drowsiness, sleepwalking, and disorientation have been reported. Researchers have hypothesized that certain people should not use melatonin supplements, including **pregnant** (page 363) or breast-feeding women, people with **depression** (page 145) or **schizophrenia** (page 393), and those with autoimmune disease, including **lupus** (page 421), at least until more is known.<sup>40, 41</sup>

In one study, administration of 3 mg per day of melatonin for three months resulted in a marked decline in sperm counts and a decline in sperm quality in

two of eight healthy young men.<sup>42</sup> In one of these two men, sperm count and quality became normal after melatonin was discontinued. Although this was a small study, it raises the possibility that long-term use of melatonin could lead to infertility.

In a group of children suffering from neurological disorders, 1–5 mg of melatonin per night led to an increase in the rate of seizures despite the fact that sleep improved.<sup>43</sup> Until more is known, children with neurological conditions should take melatonin only under medical supervision.

Many other side effects have been attributed to melatonin supplementation, including inhibition of sex drive, severe headaches, abdominal cramps, and formation of rudimentary breasts in men.<sup>44, 45</sup> However, these associations have not been supported by solid evidence.<sup>46, 47, 48, 49</sup> Since none of these claims have been well documented or independently confirmed, these problems may not have been due to melatonin.

Though most research reports that melatonin improves the quality of sleep, at least one trial has found that four of fifteen men given melatonin had their sleep patterns disturbed by supplemental melatonin.<sup>50</sup>

One case of painful gynecomastia (enlarged breasts) has been reported involving a 56-year-old man who had been suffering from amyotrophic lateral sclerosis (Lou Gehrig's disease), and was taking 1–2 mg melatonin per day for one and a half years.<sup>51</sup> As the signs and symptoms disappeared after melatonin was discontinued, the authors of the report suspected that melatonin caused this side effect.

According to a preliminary report, blood levels of melatonin may be elevated in women with **fibromyalgia** (page 191).<sup>52</sup> Data in this report did not indicate toxicity from melatonin, nor did the report suggest that melatonin causes or exacerbates the symptoms of fibromyalgia. It *did* suggest there is no current rationale for melatonin supplementation in people with fibromyalgia.

One-time oral administration of 1 mg of melatonin to post-menopausal (page 311) women reduced glucose tolerance and insulin sensitivity when tested 45 minutes after administration.<sup>53</sup> This finding suggests that people with **diabetes** (page 152) should use melatonin with caution and only under the supervision of a doctor.

### Special United Kingdom considerations

Melatonin is either not available or may require a prescription. People should check with their physicians.

## METHIONINE

### What is it?

Methionine is one of the essential **amino acids** (page 465) (building blocks of protein), meaning that it cannot be produced by the body, and must be provided by the diet. It supplies **sulfur** (page 590) and other compounds required by the body for normal metabolism and growth. Methionine also belongs to a group of compounds called lipotropics, or chemicals that help the liver process fats (lipids). Others in this group include **choline** (page 546), **inositol** (page 537), and **betaine** (page 472) (trimethylglycine).

People with **AIDS** (page 239) have low levels of methionine. Some researchers suggest this may explain some aspects of the disease process,<sup>1, 2, 3</sup> especially the deterioration that occurs in the nervous system that can cause symptoms, including **dementia** (page 19).<sup>4, 5</sup> A preliminary study has suggested that methionine (6 grams per day) may improve memory recall in people with AIDS-related nervous system degeneration.<sup>6</sup>

Other preliminary studies have suggested that methionine (5 grams per day) may help treat some symptoms of **Parkinson's disease** (page 345).<sup>7</sup> However, another form of methionine, S-adenosylmethionine (**SAMe** [page 583]) may worsen the symptoms of Parkinson's disease and should be avoided until more is known.<sup>8, 9, 10, 11, 12</sup>

Methionine (2 grams per day) in combination with several **antioxidants** (page 467), reduced **pain** (page 338) and recurrences of attacks of pancreatitis in a small but well-controlled trial.<sup>13</sup>

### Where is it found?

Meat, fish, and dairy are all good sources of methionine. Vegetarians can obtain methionine from whole grains, but beans are a relatively poor source of this **amino acid** (page 465).

**Methionine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Pancreatitis</b> (page 341) <b>Parkinson's disease</b> (page 345)
★☆☆	<b>HIV support</b> (page 239) Liver support

### Who is likely to be deficient?

Most people consume plenty of methionine through a typical diet. Lower intakes during **pregnancy** (page 363) have been associated with **neural tube defects** (page 63) in newborns, but the significance of this is not yet clear.<sup>14</sup>

### How much is usually taken?

**Amino acid** (page 465) requirements vary according to body weight. However, average-size adults require approximately 800–1,000 mg of methionine per day—an amount easily obtained or even exceeded by most Western diets.

### Are there any side effects or interactions?

Animal studies suggest that diets high in methionine, in the presence of B-vitamin deficiencies, may increase the risk for **atherosclerosis** (page 38) (hardening of the arteries) by increasing blood levels of **cholesterol** (page 223) and a compound called **homocysteine** (page 235).<sup>15</sup> This idea has not yet been tested in humans. Excessive methionine intake, together with inadequate intake of **folic acid** (page 520), **vitamin B<sub>6</sub>** (page 600), and **vitamin B<sub>12</sub>** (page 601), can increase the conversion of methionine to homocysteine—a substance linked to **heart disease** (page 98) and **stroke** (page 419). Even in the absence of a deficiency of **folic acid** (page 520), **B<sub>6</sub>** (page 600), or **B<sub>12</sub>** (page 601), megadoses of methionine (7 grams per day) have been found to cause elevations in blood levels of homocysteine.<sup>16</sup> Whether such an increase would create a significant hazard for humans taking supplemental methionine has not been established. Supplementation of up to 2 grams of methionine daily for long periods of time has not been reported to cause any serious side effects.<sup>17</sup>

## METHOXYISOFLAVONE

### What is it?

Methoxyisoflavone is a member of the family of **flavonoids (isoflavones)** (page 516). In a U.S. patent, the developers of this substance claim, based on preliminary animal research, that it possesses muscle-building and bone-building (anabolic) effects without the side effects seen with either androgenic (male) hormones or estrogenic (female) hormones.<sup>1</sup>

### Where is it found?

Several substances similar to methoxyisoflavone are found in many plants and some foods, including soybeans. Whether methoxyisoflavone itself is found in nature is unknown.

**Methoxyisoflavone has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Athletic performance</b> (page 43)

### Who is likely to be deficient?

Methoxyisoflavone is not an essential nutrient, so no deficiencies are possible.

### How much is usually taken?

Manufacturers of methoxyisoflavone recommend 200 to 400 mg twice a day.

### Are there any side effects or interactions?

Hormones with anabolic effects on muscle often have side effects that include **acne** (page 4), male-pattern baldness, prostate enlargement, and lower high-density lipoprotein (HDL; “good”) **cholesterol** (page 223). Whether methoxyisoflavone can cause these side effects has not been investigated.

## METHYLSULFONYLMETHANE

### What is it?

Methylsulfonylmethane (MSM) is a naturally occurring, organic, **sulfur** (page 590)-containing compound related to another sulfur-containing substance, dimethyl sulfoxide (**DMSO** [page 508]). MSM is found in small amounts throughout nature and has been detected in small amounts in the blood and urine of humans.<sup>1</sup>

Animal studies have shown that sulfur from oral supplements of MSM is incorporated into body proteins.<sup>2</sup> Animal studies have also reported that joints affected by **osteoarthritis** (OA [page 328]) have lower sulfur content,<sup>3</sup> and mice with arthritis given MSM, experience less joint deterioration.<sup>4</sup> According to a preliminary report, a double-blind trial in people with OA found that MSM, in the amount of 2,250 mg per day, reduced **pain** (page 338) after six weeks.<sup>5</sup>

### Where is it found?

A precursor of MSM is formed initially by ocean plankton and released into the atmosphere, where it interacts with ozone and sunlight and returns to earth as MSM in rainfall. MSM can be taken up by plants and incorporated into their structure, but no measurement of the MSM content of foods has been done. Supplements containing MSM are available.

**MSM has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Osteoarthritis (page 328)

### Who is likely to be deficient?

Although MSM is present in food, it is not an essential nutrient, so deficiency is not likely.

### How much is usually taken?

Some authorities report anecdotally that 250–500 mg per day has beneficial effects on a variety of health problems.<sup>6</sup> However, the only controlled trial using MSM used over 2000 mg per day to treat **osteoarthritis** (page 328). More research is needed before reliable recommendations for MSM supplementation can be made.

### Are there any side effects or interactions?

According to some anecdotal reports, MSM has been used in human research for many years in amounts above 2000 mg per day with no significant adverse effects.<sup>7</sup> However, **diarrhea** (page 163), skin rash, headache, and fatigue may be experienced in less than 20% of people, according to other anecdotal reports. Detectable levels of MSM in the brain of a person taking MSM supplements have been reported,<sup>8</sup> but the significance of this finding, if any, is unclear.

## MOLYBDENUM

### What is it?

Molybdenum is an essential trace mineral needed for the proper function of certain enzyme-dependent processes, including the metabolism of **iron** (page 540).

Preliminary evidence indicates that molybdenum, through its involvement in detoxifying sulfites, might

reduce the risk of sulfite-reactive **asthma** (page 32) attacks.<sup>1</sup> However, a physician should be involved in the evaluation and treatment of sulfite sensitivity.

### Where is it found?

The amount of molybdenum in plant foods varies significantly and is dependent upon the mineral content of the soil. The best sources of this mineral are beans, dark green leafy vegetables, and grains. Hard tap water can also supply molybdenum to the diet. Molybdenum is also available as a supplement.

**Molybdenum has been used in connection with the following condition** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Asthma (page 32)

### Who is likely to be deficient?

Although molybdenum is an essential mineral, no deficiencies have been reported in humans.

### How much is usually taken?

No recommended dietary allowance (RDA) has been established for molybdenum. The estimated range recommended by the Food and Nutrition Board as safe and adequate is 75–250 mcg per day for adults.

### Are there any side effects or interactions?

Molybdenum is needed to convert purine to uric acid, and excessive intake could, in rare cases, increase uric acid levels and potentially trigger **gout** (page 208). Molybdenum interferes with the absorption of copper; long-term supplementation with molybdenum could, in theory, result in copper deficiency. Molybdenum has been reported to cause psychosis in a patient taking 300 to 800 mcg per day for 18 days. This report is as yet unsubstantiated by any other human or animal research.<sup>2</sup>

## MULTIPLE VITAMIN-MINERAL SUPPLEMENTS

### What do they do?

Multiple vitamin-mineral (MVM) supplements, sometimes known as multivitamin-mineral supplements,

contain a variable number of essential and/or non-essential nutrients. Their primary purpose is to provide a convenient way to take a variety of supplemental nutrients from a single product, in order to prevent vitamin or mineral deficiencies, as well as to achieve higher intakes of nutrients believed to be of benefit above typical dietary levels.

Many MVMs contain at least 100% of the Daily Value (DV) or the U.S. Recommended Dietary Allowance (USRDA) of all vitamins that have been assigned these recommended values. Mineral levels may be lower, or in the case of high potency MVMs, most or all mineral levels may also be at 100% of DV or USRDA. Micronutrients that should be included in a complete MVM are **vitamin A** (page 595) (or **beta-carotene** [page 469]), **vitamin B-complex** (page 603) (**thiamine** [page 597], **riboflavin** [page 598], **niacin** [page 598] and/or **niacinamide** [page 598]), **vitamin B<sub>6</sub>** [page 600], **folic acid (folate)** [page 520], **vitamin B<sub>12</sub>** [page 601], **pantothenic acid** [page 568], and **biotin** [page 473]), **vitamin C** (page 604), **vitamin D** (page 607), and **vitamin E** (page 609), and the minerals **calcium** (page 483), **magnesium** (page 551), **zinc** (page 614), **iodine** (page 538), **selenium** (page 584), **copper** (page 499), **manganese** (page 553), **chromium** (page 493), **molybdenum** (page 559), and possibly **iron** (page 540). Some MVMs also contain vitamin K, but people taking the medication warfarin (Coumadin) should consult their doctor before taking vitamin K supplements. **Phosphorus** (page 570) is another essential dietary mineral, but is so abundant in the diet that it does not need to be included in an MVM formula. The only exception is for elderly people, whose diets tend to be lower in phosphorus. Calcium interferes with phosphorus absorption, so older people who are taking a calcium supplement might benefit from taking additional phosphorus.<sup>1</sup>

**Potassium** (page 572) is an unusual case, as adequate amounts of potassium cannot, by law, be sold in nonprescription products. Thus potassium, when included in an MVM formula, represents only a trivial amount. MVMs may contain **iron** (page 540), but these should be taken only by people who have been diagnosed as having, or being at high risk of, **iron deficiency** (page 278), or who have a history of frequent iron deficiency.

Some nutrients may be beneficial at levels above what is possible to obtain from diet alone, and an MVM formula can provide these levels as well. Nutri-

ents that may be useful to most people in larger amounts include **vitamin C** (page 604), **folic acid** (page 520), and **calcium** (page 483). **Vitamin E** (page 609) has long been thought to protect against **heart disease** (page 98) beginning at 100 IU per day, but more recent research has cast doubt on the value of vitamin E for heart-disease prevention.<sup>2</sup> Large amounts of **vitamin B<sub>1</sub>** (page 597), **vitamin B<sub>2</sub>** (page 598), **vitamin B<sub>3</sub>** (page 598), and **pantothenic acid** (page 568) are often included in MVM formulas. Some people claim to experience improvements in mood, energy, and/or overall well-being when taking higher-than-RDA amounts of **B vitamins** (page 603). While there is not a great deal of scientific research to support those observations, one double-blind study of healthy volunteers found that an MVM supplement significantly reduced anxiety and perceived stress levels, and possibly improved energy and the ability to concentrate.<sup>3</sup>

The importance of including the nonessential nutrient **beta-carotene** (page 469) in MVMs remains speculative. The synthetic beta-carotene found in most MVMs clearly does not prevent **cancer** (page 87) and may increase the risk of **lung cancer** (page 298) in smokers. Therefore, the inclusion of synthetic beta-carotene in MVM formulas is of questionable value, and it should be avoided by smokers. This concern was validated by the results of a large study in which male smokers who supplemented with synthetic beta-carotene had an 18% increase in incidence of lung cancer, compared with those given a placebo.<sup>4</sup> On the other hand, because beta-carotene can be converted to **vitamin A** (page 595) without causing vitamin A toxicity, some manufacturers use beta-carotene as a source of vitamin A. In contrast to synthetic beta-carotene, however, natural beta-carotene and several other **carotenoids** (page 488) may be helpful in preventing certain diseases, including some cancers.<sup>5, 6, 7</sup> Increasingly, natural beta-carotene and several other carotenoids are found in higher quality MVMs.

Another class of non-essential nutrients is the **flavonoids** (page 516), which have **antioxidant** (page 467) and other properties and have been reported by some,<sup>8</sup> though not all,<sup>9</sup> researchers to be linked with a reduced risk of **heart disease** (page 98). MVM supplements also frequently include other nutrients of uncertain benefit in the small amounts supplied, such as **choline** (page 546), **inositol** (page 537), and various **amino acids** (page 465).

Preliminary and double-blind trials have shown that

women who use an MVM containing **folic acid** (page 520), beginning three months before becoming pregnant and continuing through the first three months of **pregnancy** (page 363),<sup>10, 11</sup> have a significantly lower risk of having babies with **neural tube defects** (page 63) (e.g., spina bifida) and other congenital defects.

In one double-blind trial, schoolchildren received, for three months, a daily low-potency vitamin-mineral tablet containing 50% of the USRDA for most essential vitamins and the minerals.<sup>12</sup> The subjects were “working class,” primarily Hispanic, children, aged 6 to 12 years. Dramatic gains in certain measures of IQ were observed in about 20% of the supplemented children. These gains may have been due to the correction of specific nutrient deficiencies (for example, iron) found in these children. However, it was not possible in this study to identify which nutrients caused the increases in IQ.

#### What about “one-per-day” multiples?

One-per-day multiples are primarily **B-complex** (page 603) vitamins, with both **vitamin A** (page 595) and **vitamin D** (page 607) included either at high or low potency, depending on the supplement. The rest of the formula tends to be low potency. It does not take much of some of the minerals—for example, **copper** (page 499), **zinc** (page 614), and **iron** (page 540)—to offer 100% or more of what people normally require, so these minerals may appear at reasonable levels in a one-per-day MVM.

One-per-day MVMs usually do not provide sufficient amounts of many nutrient supplements shown to benefit people eating a Western diet, such as **vitamin E** (page 609), **calcium** (page 483), **magnesium** (page 551), and **vitamin C** (page 604). One-per-day MVMs should therefore not be viewed as a way to “cover all bases” in the way that high-potency MVMs, requiring three or more pills per day, are viewed.

#### How much is usually taken?

The following table shows the USRDA for nutrients as well as suggested optimum amounts of each vitamin and mineral that should be present in a daily MVM supplement for healthy people. Some people may want to take larger amounts because of specific health concerns. They should read the individual nutrient sections to learn about safe upper ranges of supplementation.

Nutrient	Daily Value (includes diet)	Suggested Daily Optimum in an MVM Supplement
<b>Biotin</b> (page 473)	300 mcg	300 mcg
<b>Calcium</b> (page 483)	1,000 mg	800–1,000 mg
<b>Chromium</b> (page 493)	120 mg	120–200 mcg
<b>Copper</b> (page 499)	2 mg	1–3 mg
<b>Folate</b> (page 520)	400 mcg	400 mcg
<b>Iodine</b> (page 538)	150 mcg	150 mcg
<b>Iron</b> (page 540)	18 mg	People should avoid iron supplements unless they have been diagnosed with having, or being at high risk of, <b>iron deficiency</b> (page 278).
<b>Magnesium</b> (page 551)	400 mg	250–400 mg
<b>Manganese</b> (page 553)	2 mg	2–5 mg
<b>Molybdenum</b> (page 559)	75 mcg	75 mcg
<b>Niacin</b> (page 598)	20 mg	20 mg
<b>Pantothenic acid</b> (page 568)	10 mg	10 mg
<b>Riboflavin</b> (page 598)	1.7 mg	1.7 mg
<b>Selenium</b> (page 584)	70 mcg	100–200 mcg
<b>Thiamine</b> (page 597)	1.5 mg	1.5 mg
<b>Vitamin A</b> (page 595)	5,000 IU	5,000 IU (as natural beta-carotene)
<b>Vitamin B<sub>6</sub></b> (page 600)	2 mg	10 mg
<b>Vitamin B<sub>12</sub></b> (page 601)	6 mcg	50 mcg
<b>Vitamin C</b> (page 604)	60 mg	100–200 mg
<b>Vitamin D</b> (page 607)	400 IU	400 IU
<b>Vitamin E</b> (page 609)	30 IU	30–400 IU
<b>Vitamin K</b> (page 612)	80 mcg	80 mcg
<b>Zinc</b> (page 614)	15 mg	15–25 mg

Because one-per-day formulas typically do not contain even the minimum recommended amounts of some of the nutrients listed here, multiples requiring several capsules or tablets per day are preferable. With two- to six-per-day multiples, intake should be spread out at two or three meals each day, instead of taking them all at one sitting. The amount of vitamins and minerals can be easily increased or decreased by taking more or fewer of the multiple.

#### **Which is better—capsule or tablet?**

Multiples are available as a powder inside a hard-shell pull-apart capsule, as a liquid inside a soft-gelatin capsule, or as a tablet.

Most multiples have all the ingredients mixed together. Occasionally the **B vitamins** (page 603) react with the rest of the ingredients in the capsule or tablet. This reaction, which is sped up in the presence of moisture or heat, can cause the B vitamins to “bleed” through the tablet or capsule, discoloring it and also making the multiple smell. While the multiple is still safe and effective, the smell is off-putting and usually not very well tolerated. Liquid multiples in a soft-gel capsule—or tablets or capsules that are kept dry and cool—do not have this problem.

Capsules are usually not as large as tablets, and thus some people find capsules easier to swallow.

Some people prefer vegetarian multiples. While some capsules are made from vegetarian sources, most come from animal gelatin. Vegetarians need to carefully read the label to ensure they are getting a vegetarian product.

One concern people have with tablets is whether they will break down sufficiently to allow the nutrients to be absorbed. Properly made tablets and capsules will dissolve readily in the stomach.

#### **What about timed-release?**

Some multiples are in timed-release form. The theory is that releasing vitamins and minerals slowly into the body over a period of time is better than releasing all of the nutrients at once. Except for work done on **vitamin C** (page 604)—some of which showed timed-release C was better absorbed than non-timed-release—research on this question has been lacking. It is possible that some nutrients, especially minerals, will be poorly absorbed from timed-release multiples. Also, some doctors have concerns about the safety of ingesting the chemicals that are used in tablets or capsules to make them timed-release.

#### **What about nutrient interactions?**

Another area of controversy is whether all of the nutrients in a multiple would be better utilized if they were taken separately. While certain nutrients compete with each other for absorption, this is also the case when the nutrients are supplied in food. For example, **magnesium** (page 551), **zinc** (page 614), and **calcium** (page 483) compete; **copper** (page 499) and zinc also compete. However, the body is designed to cope with this competition, which should not be a problem if multiples are spread out over the day.

#### **What about chewables?**

Unfortunately, multiples do not taste very good. In order to make chewable multiples palatable, whether for children or adults, some compromises must be made. First, bad-tasting ingredients must be reduced or eliminated. Second, the rest of the ingredients must be masked with a sweetener.

Unless an artificial sweetener like aspartame (NutraSweet) or saccharin is used, the only sweeteners available are sugars. Generally, consuming sugar is undesirable, and not having it in a chewable dietary supplement would be preferable. Xylitol, a natural sugar rarely used in chewables because it is relatively expensive, would be an ideal choice since it does not cause tooth decay or other known problems.

Some chewables, such as **vitamin C** (page 604), contain more sugar than any other ingredient. In such products, the sweetener should be listed as the first ingredient, but often is not. Care needs to be exercised when reading labels about chewable vitamins. If it tastes sweet, it contains sugar or a synthetic sweetener. In addition, chewable vitamin C products should contain buffered vitamin C, rather than the acidic form, ascorbic acid, in order to avoid damaging dental enamel.

#### **When is the best time to take a multiple?**

The best time to take vitamins or minerals is with meals. Multiples taken between meals sometimes cause **stomach upset** (page 260) and are likely not to be as well absorbed.

## **N-ACETYL CYSTEINE**

#### **What is it?**

N-acetyl cysteine (NAC) is an altered form of the **amino acid cysteine** (page 502), which is commonly found in food and synthesized by the body.

NAC helps break down mucus. Double-blind research has found that NAC supplements improved symptoms and prevented recurrences in people with chronic **bronchitis** (page 80).<sup>1, 2, 3</sup> NAC may also protect lung tissue through its **antioxidant** (page 467) activity.<sup>4</sup>

NAC helps the body synthesize **glutathione** (page 531), an important antioxidant. In animals, the antioxidant activity of NAC protects the liver from the adverse effects of exposure to several toxic chemicals. NAC also protects the body from acetaminophen toxicity and is used at very high levels in hospitals for patients with acetaminophen poisoning. It has also been shown to be effective at treating liver failure from causes other than acetaminophen poisoning (e.g., **hepatitis** [page 220], and other drug toxicity)<sup>5</sup> and at preventing kidney damage caused by injections of iopromide, a contrast medium used in people scheduled to undergo computerized tomography (CT) imaging.<sup>6</sup>

Supplementation with NAC has been shown to reduce the proliferation of certain cells lining the colon and may reduce the risk of **colon cancer** (page 123) in people with recurrent polyps in the colon.<sup>7</sup>

There have been several case reports of oral NAC producing dramatic improvements in Unverricht-Lundborg disease, an inherited degenerative disorder involving seizures and progressive disability.<sup>8, 9</sup> One study used 3 grams of NAC per day.

Oral supplementation with NAC has been used successfully in two cases to treat a rare syndrome that complicates kidney dialysis.<sup>10</sup> This condition, known as pseudoporphyria, has no other known treatment. Controlled clinical trials are needed to confirm these preliminary observations.

People undergoing a certain cardiac procedure (coronary angiography) are at risk of developing kidney damage from the injected dye that is used to visualize the coronary arteries. In a double-blind study, oral administration of NAC reduced by 86% the incidence of kidney damage in people undergoing this procedure.<sup>11</sup> The amount of NAC used in that study was 400 mg twice a day, on the day before and the day of the procedure.<sup>12</sup> Other studies have shown that NAC is protective only when a low dose of dye is used.

#### Where is it found?

**Cysteine** (page 502), the **amino acid** (page 465) from which NAC is derived, is found in most high-protein foods. NAC is not found in the diet.

**N-acetyl cysteine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Acetaminophen poisoning <b>Bronchitis</b> (page 80) (chronic) <b>Chronic obstructive pulmonary disease</b> (page 114) (COPD)
★★☆	<b>Angina pectoris</b> (page 27) <b>Gastritis</b> (page 195) <b>Heart Attack</b> (page 212) (IV immediately following a myocardial infarction) <b>HIV support</b> (page 239) Prevention of kidney damage during coronary angiography Unverricht-Lundborg Disease
★☆☆	Pseudoporphyria

#### Who is likely to be deficient?

Deficiencies of NAC have not been defined and may not exist. Deficiencies of the related **amino acid** (page 465) **cysteine** (page 502) have been reported in **HIV-infected** (page 239) patients.<sup>13</sup>

#### How much is usually taken?

Healthy people do not need to supplement NAC. Optimal levels of supplementation remain unknown, though much of the research uses 250–1,500 mg per day.

#### Are there any side effects or interactions?

One study reported that 19% of people taking NAC orally experienced nausea, vomiting, headache, dry mouth, dizziness, or abdominal pain.<sup>14</sup> These symptoms have not been consistently reported by other researchers, however.

Although a great deal of research has shown that NAC has **antioxidant** (page 467) activity, one small study found that daily amounts of 1.2 grams or more could lead to *increased* oxidative stress.<sup>15</sup> Extremely large amounts of **cysteine** (page 502), the **amino acid** (page 465) from which NAC is derived, may be toxic to nerve cells in rats.

NAC may increase urinary zinc excretion.<sup>16</sup> Therefore, supplemental **zinc** (page 614) and **copper** (page 499) should be added when supplementing with NAC for extended periods.

## N-ACETYL-GLUCOSAMINE

### What is it?

N-acetyl-glucosamine (NAG) is a form of glucosamine, one of the building blocks of joint tissue and other connective tissues. NAG differs from **glucosamine sulfate** (page 528) and glucosamine hydrochloride; instead of a sulfur or chloride molecule, NAG has a larger, more complex molecule attached to it. As a result, NAG is an entirely different molecule than either glucosamine sulfate or hydrochloride, and it also appears to be handled by the body differently.

Over the years, numerous researchers have repeatedly demonstrated in animal and test tube studies that NAG is inferior to other forms of glucosamine in terms of absorption and utilization.<sup>1, 2, 3, 4, 5, 6, 7</sup> However, an animal study demonstrated that NAG was able to enhance the manufacture of cartilage in damaged joints.<sup>8</sup> A recent human study compared the absorption of NAG to a long chain of NAG molecules (POLY-Nag).<sup>9</sup> Results showed that orally ingested NAG and POLY-Nag are absorbed and increase the blood levels of NAG, with both forms yielding similar results. In addition, there was some conversion of both molecules to glucosamine. However, the degree of conversion still resulted in lower levels of blood glucosamine levels compared to glucosamine sulfate and glucosamine hydrochloride, which are both absorbed extremely well.<sup>10, 11</sup> Furthermore, unlike glucosamine sulfate, there have been no human clinical studies utilizing NAG to treat arthritis or other health problems.

### Where is it found?

NAG is available primarily in tablets and capsules.

### Who is likely to be deficient?

As NAG is not an essential nutrient, no deficiency states have been reported.

### How much is usually taken?

Most manufacturers recommend supplementation with 1,500 mg daily.

### Are there any side effects or interactions?

No significant side effects or interactions have yet been reported in studies on NAG.

## NADH

### What is it?

NADH (nicotinamide adenine dinucleotide) is the active coenzyme form of **vitamin B<sub>3</sub>** (page 598). It plays an essential role in the energy production of every human cell.

In the brain, increased NADH concentrations may result in improved production of essential neurotransmitters.<sup>1</sup> Large preliminary studies using oral or injected NADH to treat **Parkinson's disease** (page 345) showed reductions in physical disability and in the need for medication;<sup>2, 3</sup> however, a small, double-blind, short-term trial using injections of NADH found no significant effects.<sup>4</sup> A small, uncontrolled study showed that oral NADH improved mental function in people with **Alzheimer's disease** (page 19).<sup>5</sup> Preliminary research suggests that NADH may also help people with **depression** (page 145)<sup>6</sup> or **chronic fatigue syndrome** (page 111).<sup>7</sup> These promising results come from research conducted by the developer of the oral NADH supplement and require independent confirmation.

### Where is it found?

NADH is found in the muscle tissue of fish and poultry and cattle, as well as in food products made with yeast. However, it is not known whether the NADH from these sources can be efficiently absorbed or utilized by the body. It is also available as a nutritional supplement.

**NADH has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Chronic fatigue syndrome</b> (page 111) <b>Parkinson's disease</b> (page 345)
★☆☆	<b>Alzheimer's disease</b> (page 19) <b>Depression</b> (page 145)

### Who is likely to be deficient?

NADH deficiency is known to occur only in the presence of **vitamin B<sub>3</sub>** (page 598) deficiency, which is rare in Western society except in some **alcoholics** (page 12).

### Which form of NADH is best?

NADH appears to be a chemically unstable molecule that decomposes rapidly. For this reason, techniques have been developed to stabilize the NADH sold in tablet form. At the present time, it is not known which commercially available NADH products are most effective.

### How much is usually taken?

Researchers have used 10 mg per day, taken with water only, on an empty stomach.

### Are there any side effects or interactions?

Clinical studies of NADH using oral or intravenous administration have reported no side effects with up to one year or more of use. Longer-term use has not been evaluated.

## OCTACOSANOL

### What is it?

Octacosanol is a waxy substance naturally present in some plant oils and is the primary component of the sugar cane extract called policosanol.

Octacosanol-containing wheat germ oil was investigated decades ago as an **exercise performance** (page 43)—promoting (ergogenic) agent. These preliminary studies found that octacosanol had promising effects on endurance, reaction time, and other measures of exercise capacity.<sup>1</sup> In another trial, 1,000 mcg per day of octacosanol for eight weeks was found to improve grip strength and visual reaction time, but it had no effect on chest strength, auditory reaction time, or endurance.<sup>2</sup>

### Where is it found?

Octacosanol is a waxy substance found in vegetable oils and sugar cane (*Saccharum officinarum*). Another compound, called policosanol, contains a large amount of octacosanol, along with several similar compounds.

**Octacosanol has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Athletic performance</b> (page 43)

### Who is likely to be deficient?

Because octacosanol is not an essential bodily constituent, deficiencies do not occur.

### How much is usually taken?

When octacosanol is taken as part of policosanol, 5–10 mg of policosanol is taken twice each day with meals. For exercise performance, 1 mg per day of octacosanol has been used.

### Are there any side effects or interactions?

Long-term trials in humans using amounts up to 20 mg per day have not shown any negative effects.<sup>3</sup>

## ORNITHINE

### What is it?

Ornithine, an **amino acid** (page 465), is manufactured by the body when another amino acid, **arginine** (page 467), is metabolized during the production of urea (a constituent of urine).

Animal research has suggested that ornithine, along with arginine, may promote muscle-building activity in the body by increasing levels of growth-promoting (anabolic) hormones such as insulin and growth hormone. However, most human research does not support these claims at reasonable intake levels.<sup>1, 2, 3</sup> One study that did demonstrate increased growth hormone with oral ornithine used very high amounts (an average of 13 grams per day) and reported many gastrointestinal side effects.<sup>4</sup> One controlled study reported greater increases in lean body mass and strength after five weeks of intensive strength training in **athletes** (page 43) taking 1 gram per day each of arginine and ornithine compared with a group doing the exercise but taking a placebo.<sup>5</sup> These findings require independent confirmation.

In clinical studies on people hospitalized for surgery, generalized **infections** (page 265), **cancer** (page 87), trauma, or **burns** (page 85), supplementation with ornithine alpha-ketoglutarate (OKG) has been reported to produce several beneficial effects.<sup>6</sup> A double-blind trial evaluated the effects of OKG supplementation in elderly people recovering from acute illnesses.<sup>7</sup> Those who took 10 grams of OKG per day for two months had marked improvement in appetite, weight gain, and quality of life compared with those taking the placebo. They also had shorter recovery periods and required

fewer home visits by physicians and nurses and needed fewer medications.

Ornithine aspartate has been shown to be beneficial in people with brain abnormalities (hepatic encephalopathy) due to **liver cirrhosis** (page 290). In a double-blind trial, people with cirrhosis and hepatic encephalopathy received either 18 grams per day of L-ornithine-L-aspartate or a placebo for two weeks.<sup>8</sup> Those taking the ornithine had significant improvements in liver function and blood tests compared with those taking the placebo.

Preliminary<sup>9</sup> and controlled<sup>10</sup> studies of people with severe burns showed that supplementation with 10–30 grams of ornithine alpha-ketoglutarate per day significantly improved **wound healing** (page 319) and decreased the length of hospital stays.

### Where is it found?

As with **amino acids** (page 465) in general, ornithine is predominantly found in meat, fish, dairy, and eggs. Western diets typically provide 5 grams per day. The body also produces ornithine.

### Ornithine has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Liver cirrhosis</b> (page 290) (hepatic encephalopathy) (L-ornithine-L-aspartate) Recovery from illness (ornithine alpha-ketoglutarate)
★★☆	<b>Athletic performance</b> (page 43) (for body composition and strength)

### Who is likely to be deficient?

Since ornithine is produced by the body, a deficiency of this nonessential **amino acid** (page 465) is unlikely, though depletion can occur during growth or **pregnancy** (page 363), and after severe trauma or malnutrition.<sup>11</sup>

### How much is usually taken?

Most people would not benefit from ornithine supplementation. In human research involving ornithine, 5–10 grams are typically used per day, sometimes combined with **arginine** (page 467).

### Are there any side effects or interactions?

No side effects have been reported with the use of ornithine, except for gastrointestinal distress with intakes over 10 grams per day.

The presence of **arginine** (page 467) is needed to produce ornithine in the body, so higher levels of this **amino acid** (page 465) should increase ornithine production.

## ORNITHINE ALPHA-KETOGLUTARATE

### What is it?

The amino acids **ornithine** (page 565) and **glutamine** (page 530) are combined to form ornithine alpha-ketoglutarate (OKG).

OKG has been shown to improve protein retention, **wound repair** (page 319), and **immune function** (page 255) in hospitalized patients partly by increasing levels of growth-promoting (anabolic) hormones such as insulin and growth hormone.<sup>1</sup> In a large, well-controlled trial,<sup>2</sup> nonhospitalized elderly people benefited from 10 grams per day of OKG as they recovered from various illnesses or surgery, showing improved appetite, weight gain, muscle growth, reduced need for medical care, and improved quality of life. No studies on muscle growth in athletes using OKG have been published.

### Where is it found?

Although the **amino acids** (page 465) that comprise OKG are present in protein foods such as meat and poultry and fish, the OKG compound is found only in supplements.

### OKG has been used in connection with the following condition (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Wound healing</b> (page 319)

### Who is likely to be deficient?

A deficiency of OKG has not been reported.

### How much is usually taken?

Optimal levels remain unknown, though 10 grams per day has been used in clinical trials.

### Are there any side effects or interactions?

No side effects have been reported with the use of OKG. No clear interactions between OKG and other nutrients have been established.

## PABA

### What is it?

Para-aminobenzoic acid (PABA) is a compound that is an essential nutrient for microorganisms and some animals, but has not been shown to be essential for people. PABA is considered by some to be a member of the **vitamin B-complex** (page 603), though its actions differ widely from other B vitamins.

PABA has been reported to enhance the effects of cortisone.<sup>1</sup> It may also prevent or even reverse accumulation of abnormal fibrous tissue.

The most well-known property of PABA is as an effective sunscreen, when used topically. Oral PABA supplementation has not been shown to possess any sun screening properties.<sup>2</sup>

An isolated trial published in 1942 reported that 12 of 16 **infertile women** (page 187) were able to become **pregnant** (page 363) after supplementing with 100 mg of PABA taken four times per day for three to seven months.<sup>3</sup> The effect of PABA on fertility has not been studied in modern research.

Researchers have attempted to discover whether large amounts of PABA would be helpful in various connective tissue disorders. Although preliminary studies have reported that PABA (12 grams per day) was helpful to people with scleroderma,<sup>4,5,6</sup> a double-blind trial found that supplementation with PABA did not lead to improvement.<sup>7</sup>

Older published reports of uncontrolled investigations suggest that PABA may be helpful in a variety of conditions, including dermatomyositis,<sup>8</sup> Peyronie's disease (accumulation of abnormal fibrous tissue in the penis),<sup>9</sup> pemphigus (a severe blistering disease),<sup>10</sup> and **vitiligo** (page 443) (a disorder in which patches of skin lose their pigmentation).<sup>11</sup> However, PABA was reported to cause vitiligo in one report.<sup>12</sup>

Older preliminary reports found that PABA darkened gray hair in a minority of elderly (but not younger) people.<sup>13</sup> In these trials, between 200 and 600 mg of PABA was taken per day for several months, in some cases accompanied by other **B vitamins** (page 603). However, at least one other study found that

PABA did not darken gray hair.<sup>14</sup> Therefore, the evidence supporting the use of PABA as a way to return gray hair to its original color remains very weak.

### Where is it found?

PABA is found in grains and foods of animal origin.

**PABA has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Dermatitis herpetiformis</b> (page 151) Dermatomyositis <b>Infertility (female)</b> (page 187) Pemphigus Peyronie's disease Scleroderma <b>Vitiligo</b> (page 443)

### Who is likely to be deficient?

Deficiencies of PABA have not been described in humans, and most nutritionists do not consider it an essential nutrient.

### Which form of PABA is best?

PABA is available as a nutritional supplement, but because it is mildly acidic, it can cause stomach irritation when taken in large amounts. The potassium salt of PABA, called Potaba, which is available by prescription, tends to be better tolerated.

### How much is usually taken?

Small amounts of PABA are present in some **B-complex vitamins** (page 603) and **multivitamin formulas** (page 559). The amount of PABA used in the studies described above ranged from 300 mg to 12 grams per day. Anyone taking more than 400 mg of PABA per day should consult a physician.

### Are there any side effects or interactions?

No serious side effects have been reported with 300–400 mg per day. Larger amounts (such as 8 grams per day or more) may cause **low blood sugar** (page 251), rash, fever, and (on rare occasions) liver damage.<sup>15</sup> One report exists of **vitiligo** (page 443) appearing after ingestion of large amounts of PABA<sup>16</sup> and use of amounts over 20 grams per day in small children has resulted in deaths.<sup>17</sup> There is also a report of a death from toxic **hepatitis** (page 220) in a person with **lupus** (page

421), who took as much as 48 grams per day for six days, followed by 8 grams per day for seven months.<sup>18</sup>

No interactions between PABA and other nutrients have been reported. However, PABA interferes with sulfa drugs (a class of antibiotics) and therefore should not be taken when these medications are being used.

## PANTOTHENIC ACID

### What is it?

Pantothenic acid, also called vitamin B<sub>5</sub>, is a water-soluble vitamin involved in the Kreb's cycle of energy production and is needed to make the neurotransmitter acetylcholine. It is also essential in producing, transporting, and releasing energy from fats. Synthesis of cholesterol (needed to manufacture **vitamin D** (page 607) and steroid hormones) depends on pantothenic acid. Pantothenic acid also activates the adrenal glands.<sup>1</sup> Pantethine—a byproduct of pantothenic acid—has been reported to lower blood levels of **cholesterol** (page 223) and **triglycerides** (page 235).

### Where is it found?

Liver, yeast, and salmon have high concentrations of pantothenic acid, but most other foods, including vegetables, dairy, eggs, grains, and meat, also provide some pantothenic acid.

**Pantothenic acid or pantethine have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>High cholesterol</b> (page 223) (pantethine) <b>High triglycerides</b> (page 235) (pantethine)
★★☆	<b>Rheumatoid arthritis</b> (page 387) (pantothenic acid)
★☆☆	<b>Acne</b> (page 4) (pantothenic acid) <b>Lupus</b> (page 421)

### Who is likely to be deficient?

Pantothenic acid deficiencies may occur in people with **alcoholism** (page 12) but are generally believed to be rare.

### How much is usually taken?

Most people do not need to supplement with pantothenic acid. However, the 10–25 mg found in many

**multivitamin** (page 559) supplements might improve pantothenic acid status. So-called primitive human diets provided greater amounts of this nutrient than is found in modern diets. Most cholesterol researchers using pantethine have given people 300 mg three times per day (total 900 mg).

### Are there any side effects or interactions?

No serious side effects have been reported, even at intakes of up to 10,000 mg (10 grams) per day. Very large amounts of pantothenic acid (several grams per day) can cause **diarrhea** (page 163).

Pantothenic acid works together with **vitamin B<sub>1</sub>** (page 597), **vitamin B<sub>2</sub>** (page 598), and **vitamin B<sub>3</sub>** (page 598) to help make the fuel our bodies run on—ATP.

There is one report of a 76-year-old woman who developed a life-threatening condition (eosinophilic pleuropericardial effusion) while taking 300 mg of pantothenic acid per day and 10 mg of biotin per day.<sup>2</sup> However, it is not clear whether the vitamins caused the problem.

## PHENYLALANINE

### What are they?

L-phenylalanine (LPA) serves as a building block for the various proteins that are produced in the body. LPA can be converted to **L-tyrosine** (page 544) (another **amino acid** [page 465]) and subsequently to L-dopa, norepinephrine, and epinephrine. LPA can also be converted (through a separate pathway) to phenylethylamine, a substance that occurs naturally in the brain and appears to elevate mood.

D-phenylalanine (DPA) is not normally found in the body and cannot be converted to L-tyrosine, L-dopa, or norepinephrine. As a result, DPA is converted primarily to phenylethylamine (the potential mood elevator). DPA also appears to influence certain chemicals in the brain that relate to **pain** (page 338) sensation.

DLPA is a mixture of LPA and its mirror image DPA. DLPA (or the D- or L-form alone) has been used to treat **depression** (page 145).<sup>1,2</sup> DPA may be helpful for some people with **Parkinson's disease** (page 345)<sup>3</sup> and has been used to treat chronic pain—including pain from **osteoarthritis** (page 328) and **rheumatoid arthritis** (page 387)—with both positive<sup>4</sup> and negative<sup>5</sup> results. No research has evaluated the effectiveness of DLPA on rheumatoid arthritis.

### Where are they found?

LPA is found in most foods that contain protein. DPA does not normally occur in food. However, when phenylalanine is synthesized in the laboratory, half appears in the L-form and the other half in the D-form. These two compounds can also be synthesized individually, but it is more expensive to do so. The combination supplement (DLPA) is often used because of the lower cost and because both components exert different health-enhancing effects.

**Phenylalanine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Depression</b> (page 145) (DPA, LPA, DLPA) <b>Low back pain</b> (page 293) (DPA) <b>Pain</b> (page 328) (DPA) <b>Parkinson's disease</b> (page 345) (DPA) <b>Vitiligo</b> (page 443) (LPA)
★★☆	<b>Alcohol withdrawal support</b> (page 12) (DLPA) <b>Osteoarthritis</b> (page 328) (DPA) <b>Rheumatoid arthritis</b> (page 387) (DPA)

### Who is likely to be deficient?

People whose diets are very low in protein may develop a deficiency of LPA, although this is believed to be very uncommon. However, one does not necessarily have to be deficient in LPA in order to benefit from a DLPA supplement.

### How much is usually taken?

DLPA has been used in amounts ranging from 75–1,500 mg per day. This compound can have powerful effects on mood and on the nervous system, and therefore DLPA should be taken only under medical supervision. LPA has been used in amounts up to 3.5 grams per day. For best results, phenylalanine should be taken between meals, because the protein present in food can interfere with the uptake of phenylalanine into the brain, potentially reducing its effect.

### Are there any side effects or interactions?

The maximum amount of DLPA that is safe is unknown. However, consistent toxicity in healthy people has not been reported with 1,500 mg per day or less of DLPA, except for occasional nausea, **heartburn** (page 260), or transient headaches.

When 100 mg of LPA per 2.2 pounds body weight or more was given to animals, a variety of complex problems occurred, leading two researchers to have concerns about potential toxicity of high amounts in humans.<sup>6</sup> While these concerns were directed at LPA specifically, they are likely to be equally applicable to DLPA. Although no serious adverse effects have been reported in humans taking phenylalanine, amounts greater than 1,500 mg per day should be supervised by a doctor.

People with **phenylketonuria** (page 354) must not supplement with phenylalanine.

Some research suggests that people with **tardive dyskinesia** (page 425) may process phenylalanine abnormally. Until more is known, it makes sense for people with this condition to avoid phenylalanine supplementation.

LPA competes with several other **amino acids** (page 465) for uptake into the body and the brain. Therefore, for best results, phenylalanine should be taken between meals, or away from protein-containing foods. People taking prescription or over-the-counter medications should consult a physician before taking DLPA.

## PHOSPHATIDYLSERINE

### What is it?

Phosphatidylserine (PS) belongs to a special category of fat-soluble substances called phospholipids, which are essential components of cell membranes. PS is found in high concentrations in the brain.

According to double-blind studies, PS may help preserve, or even improve, some aspects of mental functioning in the elderly when taken in the amount of 300 mg per day for three to six months.<sup>1, 2</sup>

In patients with early **Alzheimer's disease** (page 19), placebo-controlled<sup>3</sup> and double-blind studies have shown mild benefits from PS supplementation when used in the amount of 300 mg per day for three to twelve weeks.<sup>4, 5</sup> In one double-blind study, the improvement on standardized tests of mental functioning averaged approximately 15%.<sup>6</sup> Continued improvement has been reported up to three months beyond the end of the supplementation period.<sup>7</sup>

PS is not a cure for Alzheimer's disease. While it may reduce symptoms in the short term, at best PS probably slows the rate of deterioration rather than halting the progression altogether. For example, in a six-month

trial, benefits began to fade after the fourth month.<sup>8</sup> PS affects the levels of neurotransmitters in the brain related to mood. In a preliminary trial, elderly women suffering from **depression** (page 145) who were given 300 mg of PS per day for 30 days experienced, on average, a 70% reduction in the severity of their depression.<sup>9</sup>

### Where is it found?

PS is found in only trace amounts in a typical diet. Very small amounts are present in **lecithin** (page 546). The body manufactures PS from phospholipid building blocks. PS research has used material derived from a bovine source. Currently, PS that is commercially available is derived from soy.

**Phosphatidylserine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Age-related cognitive decline (ARCD)</b> (page 8)
★★☆	<b>Alzheimer's disease</b> (page 19) <b>Depression</b> (page 145) <b>Parkinson's disease</b> (page 345)

### Who is likely to be deficient?

PS is not an essential nutrient, and therefore dietary deficiencies do not occur. Adults age 50 and older, especially those with **age-related cognitive decline** (page 8), may not synthesize enough PS, and appear most likely to benefit from supplemental PS.

### Which form is best?

Most research has been conducted with PS derived from bovine (cow) brain tissue. Due to concerns about the possibility of humans contracting infectious diseases (such as Creutzfeld-Jakob or “mad cow” disease), bovine PS is not available in the United States. The soy- and bovine-derived PS, however, are not structurally identical.<sup>10</sup> Doctors and researchers have debated whether the structural differences could be important,<sup>11, 12</sup> but so far only a few trials have studied the effects of soy-based PS.

Preliminary animal research shows that the soy-derived PS does have effects on brain function similar to effects from the bovine source.<sup>13, 14, 15</sup> An isolated un-

published double-blind human study used soy-derived PS in an evaluation of memory and mood benefits in non-demented, non-depressed elderly people with impaired memories and accompanying **depression** (page 145).<sup>16</sup> In this three-month study, 300 mg per day of PS was not significantly more effective than a placebo. In a double-blind study, soy-derived PS was administered in the amount of 300 or 600 mg per day for 12 weeks to people with **age-related memory impairment** (page 8). Compared with the placebo, soy-derived PS had no effect on memory or on other measures of cognitive function.<sup>17</sup> While additional research needs to be done, currently available evidence suggests that soy-derived PS is not an effective treatment for age-related cognitive decline.

### How much is usually taken?

Positive effects on mental function have been achieved using 200–500 mg per day of bovine PS; most studies used 300 mg per day.

### Are there any side effects or interactions?

No significant side effects associated with PS have been reported.

## PHOSPHORUS

### What is it?

Phosphorus is an essential mineral that is usually found in nature combined with oxygen as phosphate. Most of the phosphate in the human body is in bone, but phosphate-containing molecules (phospholipids) are also important components of cell membranes and lipoprotein particles, such as HDL and LDL (“good” and “bad” cholesterol, respectively). Small amounts of phosphate play important roles in numerous biochemical reactions throughout the body.

The role of phosphate-containing molecules in aerobic exercise reactions has suggested that phosphate loading might enhance **athletic performance** (page 43), though controlled research has produced inconsistent results.<sup>1, 2</sup>

### Where is it found?

Phosphorus is highest in protein-rich foods and cereal grains. In addition, phosphorus additives are used in many soft drinks and packaged foods. Phosphorus is

not often present in supplements except for certain **calcium** (page 483) supplements, such as bone meal.

**Phosphorus has been used in connection with the following condition** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Osteoporosis</b> (page 333) (for elderly people taking calcium supplements)
★★☆	<b>Athletic performance</b> (page 43)

#### Who is likely to be deficient?

Phosphorus deficiency is uncommon, because dietary intake is usually adequate.<sup>3</sup> Chronic alcoholics may become deficient in phosphorus,<sup>4</sup> and people taking large amounts of aluminum-containing antacids<sup>5</sup>

One study has shown that taking calcium can interfere with the absorption of phosphorus, which, like calcium, is important for bone health.<sup>6</sup> Although most western diets contain ample or even excessive amounts of phosphorus, older people who supplement with large amounts of calcium may be at risk of developing phosphorus deficiency. For this reason, the authors of this study recommend that, for elderly people, at least some of the supplemental calcium be taken in the form of tricalcium phosphate or some other phosphorus-containing preparation.

#### How much is usually taken?

Phosphorus supplements are unnecessary. Most multiple vitamin-mineral supplements do not contain phosphorus for this reason.

#### Are there any side effects or interactions?

People with severe kidney disease must avoid excessive phosphorus. High phosphorus intake may impair absorption of **iron** (page 540), **copper** (page 499), and **zinc** (page 614).<sup>7</sup> Based primarily on animal studies, some authorities have suggested that excess intake of phosphate is hazardous to normal calcium and bone metabolism,<sup>8</sup> but this idea has been challenged.<sup>9</sup> Phosphoric acid-containing soft drinks have been implicated in elevated **kidney stone** (page 284) risk,<sup>10, 11</sup> but not all studies have found this relationship.<sup>12</sup>

Ingestion of excessive amounts of aluminum-containing antacids (such as Di-Gel, Riopan, Maalox, or Mylanta) can cause phosphorus deficiency.

## POLICOSANOL

#### What is it?

Policosanol is a mixture of long-chain alcohols (waxes), including **octacosanol** (page 565), extracted from natural sources.

#### Where is it found?

The long-chain alcohols found in policosanol are present in many foods of plant origin. Supplemental policosanol is typically extracted from sugar cane or beeswax.

**Policosanol has been used in connection with the following condition** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>High cholesterol</b> (page 223) <b>Intermittent claudication</b> (page 276)
★★☆	<b>High triglycerides</b> (page 235)

#### Who is likely to be deficient?

Policosanol is not an essential nutrient, so no deficiencies are possible.

#### How much is usually taken?

Most studies have used 5 to 10 mg of policosanol taken twice per day.

#### Are there any side effects or interactions?

When policosanol is combined with aspirin, an increased blood-thinning effect occurs.<sup>1</sup> This suggests that policosanol should not be taken with blood-thinning drugs without the supervision of a doctor.

## POLLEN

#### What is it?

Pollen, a substance collected from the flowers of various plants, contains carbohydrates, fat, protein, and some vitamins and minerals.<sup>1</sup>

A proprietary rye pollen extract (Cernilton) has been shown to have anti-inflammatory properties,<sup>2</sup> to relax

the muscles that surround the urethra,<sup>3</sup> and to inhibit growth of prostate cells.<sup>4</sup> This rye pollen extract has been reported to improve symptoms of chronic **prostatitis** (page 377) in uncontrolled trials,<sup>5, 6, 7</sup> including a trial in which three tablets daily significantly reduced symptoms in 78% of people with uncomplicated prostatitis. However, only one of eighteen people with complications (such as scar tissue and calcifications) improved.<sup>8</sup>

Preliminary<sup>9, 10, 11</sup> and double-blind<sup>12, 13, 14</sup> trials have demonstrated that a proprietary rye pollen extract is effective at reducing the symptoms of benign prostatic hyperplasia.

A preliminary report from the Ukraine on the use of flower pollen in humans with **rheumatoid arthritis** (page 387) suggested positive effects on related disorders of the liver, gallbladder, stomach, and intestine.<sup>15</sup> Pollen extracts have been used orally to desensitize people to plants to which they are **allergic** (page 14).<sup>16, 17, 18, 19, 20</sup> For example, in a double-blind study, people with **hay fever** (page 211) allergies to grass pollen were asked to place drops of liquid grass pollen extract under their tongues daily for three weeks, using a gradually increasing concentration. After the three-week period, pollen was given twice per week at a "maintenance" level. During the next allergy season they had significantly fewer severe hay fever symptoms than a group given placebo drops.<sup>21</sup>

Melbrosia, a mixture of flower pollen, fermented bee pollen, and **royal jelly** (page 582), was reported to help relieve **menopausal** (page 311) symptoms in about one-third of women in an uncontrolled survey in Denmark.<sup>22</sup> This result agrees with an earlier, controlled study that found melbrosia (amount not stated) was more effective than a placebo for menopausal symptoms, including headache, urinary incontinence, vaginal dryness, and low vitality.<sup>23</sup> According to animal studies, melbrosia does not work by causing estrogen-like effects in body tissues.<sup>24</sup> Whether royal jelly alone might have similar effects on menopausal symptoms is unknown.

### Where is it found?

Most noncultivated plants produce pollen. Commercial pollen is collected from bees returning to their hives (bee pollen) or may be directly harvested with machines (flower pollen). It is not clear which plants produce the most effective pollens. Some of the most common pollens used are timothy grass, corn, rye, and pine.

**Pollen has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Benign prostatic hyperplasia</b> (page 58) (rye)
★★☆	<b>Prostatitis</b> (page 377) (rye)

### Who is likely to be deficient?

Since pollen is not an essential bodily constituent, deficiencies do not occur.

### How much is usually taken?

The optimal intake of pollen is unknown. Some doctors recommend using 500 mg two to three times per day. Research on the proprietary rye pollen extract has used three to six tablets, or four capsules, per day.

### Are there any side effects or interactions?

Many people have **allergies** (page 14) to inhaled pollens. Allergic reactions to ingested pollen (some of them quite serious) have also been reported.<sup>25, 26, 27</sup> Otherwise, no significant adverse effects have been reported.

## POTASSIUM

### What is it?

Potassium is an essential mineral needed to regulate water balance, levels of acidity, **blood pressure** (page 246), and neuromuscular function. This mineral also plays a critical role in the transmission of electrical impulses in the heart.

People with low blood levels of potassium who are undergoing heart surgery are at an increased risk of developing **heart arrhythmias** (page 93) and an increased need for cardiopulmonary resuscitation.<sup>1</sup> Potassium is also required for carbohydrate and protein metabolism.

### Where is it found?

Most fruits are excellent sources of potassium. Beans, milk, and vegetables contain significant amounts of potassium.

**Potassium has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>High blood pressure</b> (page 246) (for people not taking potassium-sparing diuretics) <b>Kidney stones</b> (page 284) (citrate in combination with <b>magnesium</b> [page 551] citrate)
★★☆	<b>Cardiac arrhythmia</b> (page 93) <b>Congestive heart failure</b> (page 134) <b>Premenstrual syndrome</b> (page 368) <b>Stroke</b> (page 419)

#### Who is likely to be deficient?

So-called primitive diets provided much greater levels of potassium than modern diets, which may provide too little. Gross deficiencies, however, are rare except in cases of prolonged vomiting, **diarrhea** (page 163), or use of "potassium-depleting" diuretic drugs. People taking one of these drugs are often advised by their doctor to take supplemental potassium. Prescription amounts of potassium provide more than the amounts sold over the counter but not more than the amount found in several pieces of fruit.

#### How much is usually taken?

The best way to obtain extra potassium is to eat several pieces of fruit per day, as well as liberal amounts of vegetables. The amount of potassium found in the diet ranges from about 2.5 grams to about 5.8 grams per day. The amount allowed in supplements—99 mg per tablet or capsule—is very low, considering that one banana can contain 500 mg. One should not attempt to achieve higher potassium levels by taking large numbers of potassium pills. This concentrated form of potassium can irritate the stomach—a problem not encountered with the potassium in food.

#### Are there any side effects or interactions?

High potassium intake (several hundred milligrams at one time in tablet form) can produce stomach irritation. People using potassium-sparing drugs should avoid using potassium chloride-containing products, such as Morton Salt Substitute, No Salt, Lite Salt, and others and should not take potassium supplements, except under the supervision of a doctor. Even eating several pieces of fruit each day can sometimes cause

problems for people taking potassium-sparing drugs, due to the high potassium content of fruit.

Potassium and sodium work together in the body to maintain muscle tone, blood pressure, water balance, and other functions. Many researchers believe that part of the **blood pressure** (page 246) problem caused by too much salt (which contains sodium) is made worse by too little dietary potassium.

People with kidney failure should not take potassium supplements, except under careful medical supervision.

## PREGNENOLONE

#### What is it?

Pregnenolone serves as a precursor to other hormones, including dehydroepiandrosterone (**DHEA** [page 503]) and **progesterone** (page 577).<sup>1</sup>

The functions of pregnenolone in the body are not well known. It has been suggested the role of pregnenolone in the body is to serve as a "mother steroid" (precursor hormone). Aside from that role, it has no known functions in the body.

Many effects of pregnenolone on the nervous system have been studied. Rat studies indicate powerful memory-enhancing effects,<sup>2</sup> far beyond that of other neuroactive substances.<sup>3, 4</sup> In healthy men aged 20 to 30, administration of pregnenolone (1 mg daily) was found to improve **sleep** (page 270) quality and decrease intermittent wakefulness.<sup>5</sup>

It has been suggested this hormone may play a role in the neuroendocrine response to stress. In a study of airplane pilots subjected to stress, administration of pregnenolone (25 mg twice daily) improved performance without causing adverse side effects.<sup>6</sup> In a study of the stress response in rats, an increase in **anxiety** (page 30) was observed following administration of pregnenolone. The researchers suggested this was a beneficial response during a stressful period and was initiated through the nervous system.<sup>7</sup>

In a study of rats subjected to spinal cord injury, administration of pregnenolone in combination with the anti-inflammatory medication indomethacin (Indocin) and an immune-modulating substance (bacterial lipopolysaccharide) promoted recovery of nerve function. The effect was more pronounced with combination therapy than with any one of these substances given singly or in combinations of two.

Pregnenolone has not been studied in humans with spinal cord injuries.<sup>8</sup>

Pregnenolone appears to exhibit an antagonistic effect on the calming receptors in the brain (gamma-amino butyric acid [**GABA** (page 524)] receptors), resulting in an excitatory effect. It is possible this alteration in nervous system transmission could contribute to seizure activity.<sup>9,10</sup>

Steroid hormones are known to affect mood and behavior via effects on the nervous system. In people with either current **depression** (page 145) or a history of depression, pregnenolone in the cerebrospinal fluid (the fluid that bathes the brain) was significantly lower, than levels in healthy people. In addition, it was found that patients with active depression had lower levels of pregnenolone compared with those with a prior history of depression.<sup>11</sup>

In a double-blind study of elderly women with wrinkles, daily application of a 0.5% pregnenolone acetate cream improved the visible wrinkling of the skin. When the treatment was discontinued, the benefit was not maintained. Because the results were only temporary, it is suggested the beneficial effect of the cream was due to improved hydration of the skin.<sup>12</sup>

Researchers have reported on the use of pregnenolone in a variety of rheumatologic diseases. In a study of pregnenolone therapy (intramuscular injection, 50–600 mg daily) for **rheumatoid arthritis** (page 387), six of eleven people experienced moderate to marked improvement in symptoms of joint pain and joint mobility. The symptom improvement was apparent two to four days after therapy was initiated. In a study of 13 adults with **osteoarthritis** (page 328), pregnenolone therapy reduced the **pain** (page 338) and improved the range of motion in seven of the study participants. Pain recurred when therapy was discontinued. In a person who suffered from gouty arthritis that was unresponsive to conventional medications, pregnenolone therapy resulted in a dramatic response within three days of initiating therapy. This patient received 300 mg daily of pregnenolone (by intramuscular injection) for four weeks, followed by 200 mg weekly of pregnenolone as a maintenance amount. This study of pregnenolone therapy in rheumatologic diseases also reports a substantial benefit in patients with **systemic lupus erythematosus** (page 421) (SLE), **psoriasis** (page 379), and scleroderma. Of the 59 people reported in this paper, the only adverse effect was redness or pain at the site of injection. No systemic adverse effects were reported.<sup>13</sup>

### Where is it found?

The cells of both the adrenal gland and the central nervous system synthesize pregnenolone. Human studies show there are much higher concentrations of pregnenolone in the nervous tissue, than in the bloodstream.<sup>14</sup> Animal studies indicate the concentration of pregnenolone in the brain is ten-fold higher than that of other stress-related hormones (including **DHEA** [page 503]).<sup>15</sup> Pregnenolone is present in the blood as both free pregnenolone and a more stable form, pregnenolone-sulfate.

### Who is likely to be deficient?

Since it is not an essential nutrient, pregnenolone is not associated with a deficiency state.

### How much is usually taken?

Pregnenolone is generally available in amounts of 10 to 30 mg. It is not known what an appropriate intake is for humans or whether the benefits of taking this hormone outweigh the risks.

### Are there any side effects or interactions?

Due to its antagonistic effects on the **GABA** (page 524) receptor in the central nervous system, supplementation with pregnenolone could cause problems in people with a history of seizures. Pregnenolone supplementation may increase the levels of **progesterone** (page 577) and **DHEA** (page 503) in the body and possibly the levels of other hormones (testosterone and estradiol). In theory, pregnenolone could cause disturbances in the endocrine system, which may manifest as changes in the menstrual cycle or the development or aggravation of hormone sensitive diseases (including **breast** [page 65] and **prostate cancer** [page 371]). The side effects and interactions with other therapies are currently unknown.

## PROANTHOCYANIDINS

### What are they?

Proanthocyanidins—also called “OPCs” for oligomeric procyanidins or “PCOs” for procyanidolic oligomers—are a class of nutrients belonging to the **flavonoid** (page 516) family.

Proanthocyanidins have **antioxidant** (page 467) activity and they play a role in the stabilization of collagen and maintenance of elastin—two critical proteins in

connective tissue that support organs, joints, blood vessels, and muscle.<sup>1, 2</sup> Possibly because of their effects on blood vessels, proanthocyanidins have been reported in double-blind research to reduce the duration of **edema** (page 180) after face-lift surgery from 15.8 to 11.4 days.<sup>3</sup> In preliminary research, proanthocyanidins were reported to have anti-mutagenic activity (i.e., to prevent chromosomal mutations).<sup>4</sup>

Proanthocyanidins have been shown to strengthen capillaries in double-blind research using as little as 100 mg per day.<sup>5</sup> In another double-blind trial, French researchers reported that women with **chronic venous insufficiency** (page 116) had reduced symptoms using 150 mg per day.<sup>6</sup> In another French double-blind trial, supplementation with 100 mg taken three times per day, resulted in benefits within four weeks.<sup>7</sup>

Proanthocyanidins (200 mg per day for five weeks) have improved aspects of vision (**visual performance in the dark** (page 326) and after exposure to glare) in healthy people.<sup>8, 9</sup> A product that is high in proanthocyanidins has been shown to prevent and reverse abnormal blood clotting in smokers.<sup>10</sup>

### Where are they found?

Proanthocyanidins can be found in many plants, most notably pine bark, grape seed, and grape skin. However, **bilberry** (page 634), **cranberry** (page 664), black currant, **green tea** (page 686), black tea, and other plants also contain these **flavonoids** (page 516). Nutritional supplements containing proanthocyanidins extracts from various plant sources are available, alone or in combination with other nutrients, in herbal extracts, capsules, and tablets.

**Proanthocyanidins have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Chronic venous insufficiency</b> (page 116)
★★☆	<b>Capillary fragility</b> (page 93) <b>Retinopathy</b> (page 385)
★☆☆	<b>Pancreatic insufficiency</b> (page 341) <b>Varicose Veins</b> (page 440)

### Who is likely to be deficient?

**Flavonoids** (page 516) and proanthocyanidins are not classified as essential nutrients because their absence does not induce a deficiency state. However, proantho-

cyanidins may have many health benefits, and anyone not eating the various plants that contain them would not derive these benefits.

### How much is usually taken?

**Flavonoids** (page 516) (proanthocyanidins and others) are a significant source of **antioxidants** (page 467) in the average diet. Proanthocyanidins at 50–100 mg per day is considered a reasonable supplemental level by some doctors, but optimal levels remain unknown.

### Are there any side effects or interactions?

**Flavonoids** (page 516), in general, and proanthocyanidins, specifically, have not been associated with any consistent side effects. As they are water-soluble nutrients, excess intake is simply excreted in the urine.

## PROBIOTICS

### What are they?

Probiotic bacteria favorably alter the intestinal microflora balance, inhibit the growth of harmful bacteria, promote good digestion, boost **immune function** (page 255), and increase resistance to **infection** (page 265).<sup>1, 2</sup> People with flourishing intestinal colonies of beneficial bacteria are better equipped to fight the growth of disease-causing bacteria.<sup>3, 4</sup> Lactobacilli and bifidobacteria maintain a healthy balance of intestinal flora by producing organic compounds—such as lactic acid, hydrogen peroxide, and acetic acid—that increase the acidity of the intestine and inhibit the reproduction of many harmful bacteria.<sup>5, 6</sup> Probiotic bacteria also produce substances called bacteriocins, which act as natural antibiotics to kill undesirable microorganisms.<sup>7</sup>

**Immune function** (page 255) tends to decline with age. Twice daily supplementation with *Bifidobacterium lactis* (a particular strain of bifidobacteria) in milk was found in a double-blind trial to significantly enhance various aspects of immune function in a group of healthy elderly people.<sup>8</sup> Benefits were apparent after only six weeks of supplementation. Yogurt has been purported to support immune function, due to its inclusion of lactic-acid bacteria.<sup>9</sup> While *B. lactis* is a different organism than that found in yogurt, effects on immunity may be similar.

Regular ingestion of probiotic bacteria may help prevent **vaginal yeast infection** (page 454).<sup>10, 11</sup> A review of the research concluded that both topical and oral use

of acidophilus can prevent yeast infection caused by candida overgrowth.<sup>12</sup>

**Diarrhea** (page 163) flushes intestinal microorganisms out of the gastrointestinal tract, leaving the body vulnerable to opportunistic **infections** (page 265). Replenishing the beneficial bacteria with probiotic supplements can help prevent new infections. The incidence of “traveler’s diarrhea,” caused by pathogenic bacteria in drinking water or undercooked foods, can be reduced by the preventive use of probiotics.<sup>13</sup>

Most people associate lactobacilli with *L. acidophilus*, the most popular species in this group of probiotic bacteria. However, research shows that other *Lactobacillus* species may be beneficial as well. For example, *L. rhamnosus* and *L. plantarum* appear to be protective intestinal bacteria. They are involved in the production of several “gut nutrients,” such as short-chain fatty acids, and the **amino acids** (page 465), **arginine** (page 467), **cysteine** (page 502), and **glutamine** (page 530).<sup>14</sup> These beneficial bacteria may also help remove toxins from the gut and exert a beneficial effect on **cholesterol levels** (page 223).<sup>15</sup>

In a double-blind trial, administration of a preparation containing *L. plantarum* to people with acute pancreatitis reduced the number of complications severe enough to require surgery.<sup>16</sup>

One probiotic, *Saccharomyces boulardii*, has prevented diarrhea in several human trials.<sup>17</sup> Double-blind research studying critically ill patients found this strain of yeast to prevent diarrhea when 500 mg is taken four times per day.<sup>18</sup>

Probiotics are important in recolonizing the intestine during and after antibiotic use. Probiotic supplements replenish the beneficial bacteria, preventing up to 50% of infections occurring after antibiotic use.<sup>19</sup>

Probiotics also promote healthy **digestion** (page 260). **Enzymes** (page 506) secreted by probiotic bacteria aid digestion. Acidophilus is a source of **lactase** (page 545), the enzyme needed to digest milk sugar, which is lacking in **lactose-intolerant** (page 288) people.<sup>20</sup>

**Fructo-oligosaccharides** (page 522) (FOS) are naturally occurring carbohydrates that cannot be digested or absorbed by humans. They support the growth of bifidobacteria, one of the beneficial bacterial strains.<sup>21</sup> Due to this effect, some doctors recommend that patients taking bifidobacteria also supplement with FOS. Several trials have used 8 grams per day. However, a review of the research has suggested that 4 grams per day appears to be enough to significantly increase the amount of bifidobacteria in the gut.<sup>22</sup>

### Where are they found?

Beneficial bacteria present in fermented dairy foods—namely live culture yogurt—have been used as a folk remedy for hundreds, if not thousands, of years. Yogurt is the traditional source of beneficial bacteria. However, different brands of yogurt can vary greatly in their bacteria strain and potency. Some (particularly frozen) yogurts do not contain any live bacteria. Supplements in powder, liquid extract, capsule, or tablet form containing beneficial bacteria are other sources of probiotics.

**Probiotics have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Diarrhea</b> (page 163) <b>Tooth decay</b> (page 431) ( <i>Lactobacillus GG</i> ) <b>Vaginitis</b> (page 438) <b>Yeast infection</b> (page 454)
★★☆	<b>Canker sores</b> (page 90) <b>Colic</b> (page 121) ( <i>Bifidobacterium lactis</i> and <i>Streptococcus thermophilus</i> ) <b>Crohn's disease</b> (page 141) ( <i>Saccharomyces boulardii</i> ) <b>Eczema</b> (page 177) <b>Food allergies</b> (page 14) <b>HIV support</b> (page 239) ( <i>Saccharomyces boulardii</i> ) <b>Immune function</b> (page 255) <b>Infection</b> (page 265) <b>Pancreatitis (acute)</b> ( <i>Lactobacillus plantarum</i> ) <b>Ulcerative colitis</b> (page 433)
★☆☆	<b>Chronic candidiasis</b> (page 109)

### Who is likely to be deficient?

People using antibiotics, eating a poor diet, or suffering from **diarrhea** (page 163) are more likely to have depleted colonies of friendly bacteria.

### How much is usually taken?

The amount of probiotics necessary to replenish the intestine varies according to the extent of microbial depletion and the presence of harmful bacteria. One to two billion colony forming units (CFUs) per day of acidophilus is considered to be the minimum amount for the healthy maintenance of intestinal microflora. Some *Saccharomyces boulardii* research has used 500 mg taken four times per day.

### Are there any side effects or interactions?

There are at least nine case reports of severe, invasive (internal) fungal **infections** (page 265) developing in people treated with the yeast organism *Saccharomyces boulardii*. All of these people were debilitated or had impaired **immune function** (page 255) prior to receiving *Saccharomyces boulardii*.<sup>23, 24</sup> No such adverse reactions have been reported with other probiotic supplements or in people with normal immune systems.

Acidophilus and bifidobacteria may manufacture **B vitamins** (page 603), including **niacin** (page 598), **folic acid** (page 520), **biotin** (page 473), and **vitamin B<sub>6</sub>** (page 600).

## PROGESTERONE

### What is it?

Progesterone is a hormone from a corpus luteum, formed by the cyclical rupture of an ovarian follicle. Progesterone is necessary for proper uterine and breast development and function.

Natural progesterone and synthetic progestins are structurally different and have differing effects in the body. Progestins are recommended by doctors if estrogen is prescribed during or after **menopause** (page 311), because prolonged estrogen replacement therapy without the addition of progestins (or large amounts of natural progesterone), increases the risk of uterine cancer.<sup>1</sup> However, women who have had a hysterectomy—and therefore no longer have a uterus—are typically prescribed estrogens without progestins. Although natural progesterone is considered by some doctors to be safer and more effective for a variety of health problems, researchers have studied the effects of supplemental natural progesterone much less than the effects of synthetic progestins.

Preliminary evidence suggests that progesterone plays a role in bone metabolism and could help reduce the risk of osteoporosis.<sup>2</sup> An uncontrolled study, using topically applied natural progesterone cream in combination with diet, exercise, and **vitamin** (page 559) and **calcium** (page 483) supplementation, reported consistent gains in bone density over a three-year period in postmenopausal women. However, no comparison was made to a similar program without progesterone.<sup>3</sup>

One trial found that adding natural progesterone to estrogen therapy had no better effect on bone mass than estrogen therapy alone<sup>4</sup> and another trial reported that

progesterone applied topically over a one-year period had no effect on bone loss.<sup>5</sup> In a more recent double-blind study, progesterone had a modest bone-sparing (protective) effect in post-menopausal women.<sup>6</sup>

Some doctors have observed that progesterone administered vaginally, rectally, or topically (to the skin) can relieve the symptoms of **premenstrual syndrome** (page 368) (PMS).<sup>7</sup> However, most well-controlled studies have not found natural progesterone to be effective against PMS.<sup>8</sup>

One double-blind study found that topical administration of natural progesterone led to a reduction in hot flashes in 83% of women, compared with improvement in only 19% of those given a placebo.<sup>9</sup> Synthetic progestins have also been reported to reduce symptoms of **menopause** (page 311).<sup>10</sup>

Some studies have linked synthetic progestins to increased risk of **breast cancer** (page 65).<sup>11</sup> In contrast, topical progesterone has produced changes in breast tissue that may have a **cancer prevention** (page 87) effect.<sup>12, 13</sup> Other researchers, however, have reported essentially opposite effects, suggesting that natural progesterone may increase proliferation of breast cells.<sup>14</sup>

Looked at as a whole, the research remains incomplete and inconsistent. In one trial, (natural) progesterone deficiency was linked with an increased risk, but only when the breast cancer was diagnosed before menopause.<sup>15</sup> Such a finding fits with the idea that natural progesterone might be protective. This position is further strengthened by a preliminary trial showing that a raised level of progesterone in the blood at the time of breast cancer surgery is associated with an improved prognosis for premenopausal women with operable breast cancer.<sup>16</sup> However, most breast cancer begins postmenopausally, and one trial found that progesterone deficiency was associated with a large (though statistically nonsignificant) decreased risk of postmenopausal breast cancer.<sup>17</sup> If duplicated by future research, this finding would not suggest protection, nor even necessarily safety.

A recent report found that long-term topical use of natural progesterone on the breast neither increased nor decreased the risk of women eventually being diagnosed with breast cancer.<sup>18</sup> In this trial, some women were also taking oral synthetic progesterone-like drugs. Remarkably, women using this combination experienced a 50% decreased risk of eventually being diagnosed with breast cancer. More research is needed to understand the effects of both synthetic and natural progesterone in both pre- and postmenopausal women.

Synthetic progestins have been linked to effects that might increase the risk of **heart disease** (page 98).<sup>19</sup> However, vaginally applied natural progesterone has been reported to significantly enhance the benefits of estrogen replacement therapy on heart function in women with **coronary artery disease** (page 38).<sup>20</sup> More research is needed to evaluate the effects of natural progesterone on heart disease.

Although the differences in the chemical structure of natural progesterone and synthetic progestins are slight, their effects in the body differ considerably and the two forms should not be considered interchangeable. Synthetic progestins may be useful for **endometriosis** (page 182) and **menorrhagia** (page 314) (prolonged or profuse menstrual flow) because of their specific effects on progesterone receptors in the brain and on the glandular response of the uterine lining. However, these same effects may be detrimental for women with **PMS** (page 368), and may be associated with *increased* symptoms, such as **depression** (page 145), headaches, and **water retention** (page 180). Thus, natural progesterone may be preferable to synthetic progestins for PMS.<sup>21</sup>

### Where is it found?

Progesterone is produced in the female body in the ovaries. Progesterone production is high during the luteal phase (second portion) of the menstrual cycle and low during the follicular phase (first portion), as well as being low before puberty and after menopause.

Supplemental sources of progesterone are available in oral and cream forms, as well as lozenges, suppositories, and injectable forms. "Natural" progesterone refers to the molecule that is identical in chemical structure to the progesterone produced in the body, even if the molecule is synthesized in a laboratory.

Progestins are found in oral contraceptive pills and are used in conventional hormone replacement therapy.

**Wild yam** (page 759) contains precursors to progesterone (such as diosgenin) that can be converted through a chemical process in the laboratory into progesterone—the exact same molecule made in the human body. However, contrary to popular claims, the diosgenin in wild yams cannot be converted into progesterone in the body.<sup>22, 23</sup> Women who require progesterone should consult their physician and not rely on wild yam or other herbs.

**Pregnenolone** (page 573), another hormone produced by the body, is converted by the body into progesterone. However, it is not clear what effect supplementing with pregnenolone will have on progesterone production in the body.

**Progesterone has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Amenorrhea</b> (page 22) <b>Menopause</b> (page 311) <b>Osteoporosis</b> (page 333)
★★★	<b>Dysmenorrhea</b> (page 171) (topical cream) <b>Heart disease</b> (page 98) <b>Premenstrual syndrome</b> (page 368)

### Who is likely to be deficient?

Postmenopausal women have reduced production of progesterone. While this "deficiency" is normal, progesterone, including the natural forms of progesterone, has been found to relieve **menopausal** (page 311) symptoms when used in combination with estrogen replacement therapy.<sup>24</sup>

### How much is usually taken?

The proper amount of progesterone for a woman should be determined in consultation with a doctor. Some research with the natural, oral form of progesterone has used 200 mg per day.<sup>25</sup> Progesterone is used in much lower amounts—such as 20–70 mg per day—by most doctors who prescribe topical natural progesterone. However, the ability of skin-applied progesterone to achieve effective levels in the body is the source of considerable debate.<sup>26</sup> Although progesterone is a natural substance, oral progesterone supplements are available by prescription only. High-dose topical progesterone cream is also treated like a drug and requires a prescription. A few creams containing lower amounts of progesterone are sold without prescription.

### Are there any side effects or interactions?

Progesterone is a hormone and, as such, concerns about its inappropriate use have been raised. A physician should be consulted before using this hormone as a supplement. Few side effects have been associated with topical progesterone creams but can include skin reactions. Effects of natural progesterone on **breast cancer** (page 65) risk remain unclear. Research has suggested both increased and reduced risk.

Synthetic progestins have many well-known side effects, including the increase of LDL ("bad") **cholesterol** (page 223) and the decrease of HDL ("good") cholesterol. Other side effects reported with synthetic progestins include **bloating** (page 137), breast soreness,

**depression** (page 145), and mood swings. Natural progesterone has been shown to have no adverse effect on HDL **cholesterol** (page 223) levels.<sup>27</sup> Overall, natural progesterone is considerably safer than progestins and is therefore preferred by many doctors in situations where either would be effective.<sup>28</sup>

## PROPOLIS

### What is it?

Propolis is the resinous substance collected by bees from the leaf buds and bark of trees, especially poplar and conifer trees. Bees use the propolis along with beeswax to construct their hives.

Propolis has antibiotic activities that help the hive block out viruses, bacteria, and other organisms. Commercial preparations of propolis appear to retain these antibiotic properties, according to test tube studies.<sup>1, 2</sup> Test tube and animal studies have also shown that propolis exerts some **antioxidant** (page 467),<sup>3</sup> liver protecting,<sup>4</sup> anti-inflammatory,<sup>5, 6, 7</sup> and anticancer properties.<sup>8</sup>

Propolis contains protein, **amino acids** (page 465), vitamins, minerals, and **flavonoids** (page 516).<sup>9, 10, 11</sup> For this reason, some people use propolis as a general nutritional supplement, although it would take large amounts of propolis to supply meaningful amounts of these nutrients. Propolis may stimulate the body's **immune system** (page 255), according to preliminary human studies,<sup>12, 13</sup> and a controlled trial found propolis-containing mouthwash effective in healing surgical **wounds** (page 319) in the mouth.<sup>14</sup> In test tube studies propolis has shown considerable activity against bacteria and yeast associated with **dental cavities** (page 431), **gingivitis** (page 203), and **periodontal disease** (page 203),<sup>15, 16</sup> but one human study showed that propolis was no better than a placebo in inhibiting dental plaque formation.<sup>17</sup>

Propolis extracts may be helpful in protecting against and shortening the duration of the **common cold** (page 129).<sup>18</sup> A preliminary human study reported propolis extract (amount not stated) reduced upper respiratory infections in children.<sup>19</sup> In one small double-blind study of 50 people with the common cold, the group taking propolis extract (amount not stated) became symptom-free more quickly when compared with the placebo group.<sup>20</sup>

The antimicrobial properties of propolis may also help protect against **parasitic infections** (page 343) in

the gastrointestinal tract. One preliminary study of children and adults with giardiasis (a common intestinal parasite infection) showed a 52% success rate of parasite elimination in children and a 60% rate in adults in those given propolis extract (amount not stated).<sup>21</sup> However, these results are not as impressive as those achieved with conventional drugs used against giardiasis, so propolis should not be used alone for this condition without first consulting a physician about available medical treatment.

Topical applications of propolis-containing ointments and creams are showing promise in the treatment of certain health conditions. A controlled study found that men and women with recurrent **genital herpes** (page 200) simplex virus infections (HSV type 2) who applied an ointment containing propolis to their lesions experienced significantly faster healing compared with either a topical antiviral medication or placebo.<sup>22</sup> In a small double-blind study, women with inflammation of the cervix (cervicitis) due to infection experienced significant healing after applying a vaginal dressing containing 5% propolis for ten days.<sup>23</sup> Anti-inflammatory effects from topical application of propolis extract have been noted in one animal study,<sup>24</sup> and a preliminary controlled study found that people with **rheumatoid arthritis** (page 387) treated with topical propolis extract had greater improvements in symptoms compared with placebo.<sup>25</sup>

### Where is it found?

Propolis is available in liquid extract form as well as in capsules and tablets. Topical creams and sprays containing propolis are also available, but whether they closely resemble topical propolis products used in research is unclear.

### Propolis has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Cervicitis (topical use) <b>Common cold</b> (page 129) <b>Genital Herpes</b> (page 200) (topical use) <b>Infertility (female)</b> (page 187) (in women with endometriosis) <b>Parasites</b> (page 343) <b>Rheumatoid arthritis</b> (page 387) (topical)
★☆☆	<b>Cold Sores</b> (page 119) (topical) <b>Dental caries</b> (page 431) (topical) <b>Periodontal disease</b> (page 203) (topical)

### Who is likely to be deficient?

Propolis is not an essential nutrient and no deficiency states have been reported.

### How much is usually taken?

Most manufacturers recommend 500 mg of oral propolis products once or twice daily. For topical applications, follow label instructions.

### Are there any side effects or interactions?

Propolis is generally nontoxic, though allergic reactions have been reported.<sup>26</sup> These reactions are typically limited to skin rashes;<sup>27</sup> however, as with other bee products (e.g., **pollen** [page 571] and **royal jelly** [page 582]), more severe allergic reactions are possible. People who are allergic to bee pollen, honey, or conifer and poplar trees should not use propolis unless tested first by an allergy specialist. As the effects of propolis during pregnancy and breast-feeding have not been sufficiently evaluated, women should not use it during these times unless directed to do so by a physician.

### Where is it found?

Pyruvate is formed in the body as a byproduct of the normal metabolism of carbohydrates and protein and is present in several foods, including red apples, cheese, dark beer, and red wine. Dietary supplements of pyruvate are also available.

**Pyruvate has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★	<b>Weight loss and obesity</b> (page 446)
★★★	<b>Athletic performance</b> (page 43) (for exercise performance)
★★★	<b>Athletic performance</b> (page 43) (for improving body composition with strength training in untrained people only)

### Who is likely to be deficient?

Because it is not an essential nutrient, pyruvate is not associated with a deficiency state.

### How much is usually taken?

Most human research with pyruvate and **weight loss** (page 446) has used at least 30 grams per day. However, such large amounts may not be necessary. In a six-week double-blind trial, as little as 6 grams per day of pyruvate in combination with exercise, led to greater weight loss and loss of body fat, compared with a placebo plus exercise.<sup>14</sup>

### Are there any side effects or interactions?

High intakes of pyruvate can trigger **gastrointestinal upset** (page 195), such as gas, bloating, and **diarrhea** (page 163). One preliminary study in exercising women found 10 grams per day of pyruvate reduced blood levels of HDL (the “good” cholesterol) after one month.<sup>15</sup>

## QUERCETIN

### What is it?

Quercetin belongs to a class of water-soluble plant pigments called **flavonoids** (page 516).

Quercetin acts as an antihistamine and has anti-inflammatory properties. As an **antioxidant** (page

## PYRUVATE

### What is it?

Pyruvate (the buffered form of pyruvic acid) is a product created in the body during the metabolism of carbohydrates and protein.

Pyruvate may aid **weight loss** (page 446) efforts.<sup>1</sup> A clinical trial found that supplementation with 22–44 grams per day of pyruvate, when compared with placebo, enhanced weight loss and resulted in a greater reduction of body fat in overweight adults consuming a low-fat diet.<sup>2</sup> Three controlled studies combining 6–10 grams per day of pyruvate with an exercise program, reported similar effects on weight loss and body fat.<sup>3, 4, 5</sup> Animal studies suggest that pyruvate supplementation leads to weight loss by increasing the resting metabolic rate.<sup>6</sup> A few clinical trials also indicated that pyruvate supplements may improve **exercise endurance** (page 43),<sup>7, 8</sup> though weight-lifting capacity did not improve.<sup>9</sup>

Preliminary research indicates that pyruvate functions as an **antioxidant** (page 467), inhibiting the production of harmful free radicals.<sup>10, 11, 12</sup> Preliminary research with animals suggests that, due to its antioxidant function, pyruvate may inhibit the growth of **cancerous** (page 87) tumors.<sup>13</sup> However, this effect has not been confirmed in human studies.

467), it protects LDL **cholesterol** (page 223) ("bad" cholesterol) from becoming damaged. A variety of evidence indicates that quercetin possesses potent antioxidant properties. Cardiologists believe that damage to LDL cholesterol is an underlying cause of **heart disease** (page 98). Quercetin blocks an **enzyme** (page 506) that leads to accumulation of sorbitol, which has been linked to nerve, eye, and kidney damage in those with **diabetes** (page 152). However, no human research has demonstrated these actions of quercetin in people with diabetes patients.

Quercetin is considered a phytoestrogen (i.e., a plant substance with similar functions as that of estrogen). Some phytoestrogens are believed also to have anti-estrogenic effects that might lead to reduced risks of certain **cancers** (page 87). Quercetin was found to have this antiestrogenic activity by inhibiting **breast cancer** (page 65) cells in a test tube.<sup>1</sup>

In a double-blind trial, 67% of people taking quercetin had an improvement of **prostatitis** (page 377) symptoms, compared with a 20% response rate in the placebo group.<sup>2</sup>

#### Where is it found?

Quercetin can be found in onions, apples, **green tea** (page 686), and black tea. Smaller amounts are found in leafy green vegetables and beans.

**Quercetin has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Prostatitis</b> (page 377) (nonbacterial prostatitis, prostdynia)
★★☆	<b>Allergies</b> (page 14) <b>Asthma</b> (page 32) <b>Atherosclerosis</b> (page 38) <b>Capillary fragility</b> (page 93) <b>Childhood diseases</b> (page 105) <b>Cataracts</b> (page 101) <b>Diabetes</b> (page 152) <b>Edema (water retention)</b> (page 180) <b>Gout</b> (page 208) <b>Hay fever</b> (page 211) <b>Peptic ulcer</b> (page 349) <b>Retinopathy</b> (page 385)

#### Who is likely to be deficient?

No clear deficiency of quercetin has been established.

#### How much is usually taken?

Some doctors recommend 200–500 mg of quercetin taken two to three times per day. Optimal intake remains unknown.

#### Are there any side effects or interactions?

No clear toxicity has been identified. Early quercetin research suggested that large amounts of quercetin could cause cancer in animals.<sup>3</sup> Most,<sup>4,5,6</sup> but not all,<sup>7</sup> current research finds quercetin to be safe or actually linked to protection from **cancer** (page 87).

Quercetin has been shown to cause chromosomal mutations in certain bacteria in test tube studies.<sup>8</sup> Although the significance of this finding for humans is not clear, some doctors are concerned about the possibility that **birth defects** (page 63) could occur in the offspring of people supplementing with quercetin at the time of conception or during **pregnancy** (page 363).

Since **flavonoids** (page 516) help protect and enhance **vitamin C** (page 604), quercetin is often taken with vitamin C.

## RESVERATROL

#### What is it?

Resveratrol, a compound found primarily in red wine, is a naturally occurring **antioxidant** (page 467).

In test tube and animal studies, resveratrol decreased the "stickiness" of blood platelets and helped blood vessels remain open and flexible.<sup>1,2,3</sup> A series of laboratory experiments suggested that resveratrol inhibits the development of **cancer** (page 87) in animals and prevents the progression of cancer.<sup>4</sup> In other animal studies, resveratrol was shown to be an effective anti-inflammatory agent.<sup>5</sup> However, human research is still needed in all of these areas.

#### Where is it found?

Resveratrol is present in a wide variety of plants—of the edible plants, mainly in grapes and peanuts.<sup>6</sup> Wine is the primary dietary source of resveratrol. Red wine contains much greater amounts of resveratrol than does white wine, since resveratrol is concentrated in the grape skin and the manufacturing process of red wine includes prolonged contact with grape skins. Resveratrol is also available as a dietary supplement.

**Resveratrol has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Atherosclerosis (page 38)

#### Who is likely to be deficient?

Since it is not an essential nutrient, resveratrol is not associated with a deficiency state.

#### How much is usually taken?

An 8-ounce glass of red wine provides approximately 640 mcg of resveratrol, while a handful of peanuts provides about 73 mcg of resveratrol. Resveratrol supplements (often found in combination with grape extracts or other **antioxidants** [page 467]) are generally taken in the amount of 200–600 mcg per day. This is far less than the amount used in animal studies to prevent **cancer** (page 87): equivalent to more than 500 mg (500,000 mcg) per day for an average-sized human. Therefore, one should not assume that the small amounts found in supplements or food would necessarily be protective. The optimal level of intake is not known.

While a moderate intake of red wine may protect against **heart disease** (page 98), the optimal amount required to produce this effect is still unknown. Due to the risks involved with drinking alcohol, drinking red wine cannot be recommended as a means of preventing heart disease until more information is known.

#### Are there any side effects or interactions?

No side effects have been reported with the use of resveratrol.

## RIBOSE

#### What is it?

Ribose is a type of sugar normally made in the body from glucose. Ribose plays important roles in the synthesis of RNA, DNA, and the energy-containing substance adenosine triphosphate (ATP).

According to preliminary animal and human research, ribose supplementation speeds up regeneration of ATP in muscle cells of the heart or elsewhere in the body when those cells have been deprived of oxygen.<sup>1, 2, 3, 4</sup>

#### Where is it found?

Ribose is present in small amounts in many foods of plant or animal origin.

**Ribose has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Angina (page 27)
★☆☆	Athletic performance (page 43)

#### Who is likely to be deficient?

Ribose is not an essential nutrient, therefore deficiencies do not occur.

#### How much is usually taken?

Sports supplement manufacturers recommend 1 to 10 grams per day of ribose.

#### Are there any side effects or interactions?

No known side effects have been reported from the use of ribose when consumed in amounts of less than 10 grams per day. Larger amounts may cause gastrointestinal distress such as diarrhea,<sup>5</sup> and may lower glucose levels,<sup>6</sup> although it is not known whether symptoms of hypoglycemia might result.

## ROYAL JELLY

#### What is it?

Royal jelly is a thick, milky substance produced by worker bees to feed the queen bee. The worker bees mix honey and bee pollen with enzymes in the glands of their throats to produce royal jelly.

Royal jelly is believed to be a potentially useful supplement because of the queen bee's superior size, strength, stamina, and longevity compared to other bees, but these effects have not been studied in humans. Royal jelly contains all of the B vitamins, including high concentrations of **pantothenic acid** (page 568) (vitamin B<sub>5</sub>) and **pyridoxine** (page 600) (vitamin B<sub>6</sub>).<sup>1</sup> Other nutritional qualities of royal jelly are similar to those of pollen.<sup>2</sup>

Test tube studies suggest royal jelly may have some cancer-preventive properties.<sup>3</sup> Animal studies have found that royal jelly has some **cholesterol-lowering**

(page 223),<sup>4</sup> **immune-stimulating** (page 223),<sup>5</sup> anti-inflammatory, and **wound-healing** (page 319) properties.<sup>6</sup>

Scientific investigation into the health-promoting properties of royal jelly in humans has been limited to its ability to lower blood cholesterol levels. There have been ten human studies published, seven of which were double-blind.<sup>7</sup> Of these seven double-blind studies, only three studies utilized an oral preparation of royal jelly;<sup>8, 9, 10</sup> an injectable form was used in the other four.<sup>11, 12, 13</sup> A detailed analysis of the oral double-blind studies concluded there were many shortcomings in the design of the research, but royal jelly in amounts of 50–100 mg per day reduced total cholesterol levels by about 14% in people with moderately high cholesterol levels.<sup>14</sup>

Melbrosia, a mixture of royal jelly, flower **pollen** (page 571), and fermented bee pollen, was reported to help relieve **menopausal** (page 311) symptoms in about one-third of women in a preliminary study in Denmark.<sup>15</sup> This result agrees with an earlier, controlled study that found melbrosia (amount not stated) was more effective than placebo for menopausal symptoms, including headache, urinary incontinence, vaginal dryness, and low vitality.<sup>16</sup> According to animal studies, melbrosia does not work by causing estrogen-like effects in body tissues.<sup>17</sup> Whether royal jelly alone might have similar effects on menopausal symptoms is unknown.

#### Where is it found?

Royal jelly is available in liquid form (usually in glass vials), tablets, and capsules.

**Royal jelly has been used in connection with the following condition** (refer to it for complete information):

Rating	Health Concerns
★★☆	High cholesterol (page 223)

#### Who is likely to be deficient?

Because royal jelly is not an essential nutrient, deficiencies do not occur.

#### How much is usually taken?

Royal jelly in the amount of 50–100 mg per day has been used in most of the studies on **cholesterol** (page 223) lowering.

#### Are there any side effects or interactions?

Allergic reactions are the most common side effect. Allergic reactions from oral intake of royal jelly can range from very mild (e.g., mild gastrointestinal upset) to more severe reactions, including **asthma** (page 32), anaphylaxis (shock), intestinal bleeding, and even death in people who are extremely allergic to bee products.<sup>18, 19, 20</sup> People who are allergic to bee pollen, honey, or conifer and poplar trees should not use royal jelly orally. Topical use of royal jelly has been reported to cause skin irritations in some people.<sup>21</sup>

## SAMe

#### What is it?

S-adenosyl-l-methionine (SAMe) is an important biological agent in the human body, participating in over 40 essential biochemical reactions.

SAMe participates in detoxification reactions and in the manufacture of brain chemicals, **antioxidants** (page 467), joint tissue structures, and many other important components.<sup>1, 2</sup>

SAMe appears to raise levels of dopamine, an important neurotransmitter in mood regulation,<sup>3</sup> and higher SAMe levels in the brain are associated with successful drug treatment of **depression** (page 145).<sup>4</sup> Oral SAMe has been demonstrated to be an effective treatment for depression in some,<sup>5, 6, 7, 8</sup> though not all,<sup>9</sup> double-blind studies. While it does not seem to be as powerful as full amounts of antidepressant medications<sup>10</sup> or **St. John's wort** (page 747), its effects are felt more rapidly, often within one week.<sup>11</sup>

SAMe possesses anti-inflammatory, pain-relieving, and tissue-healing properties that may help protect the health of joints.<sup>12, 13</sup> Several double-blind studies have shown that SAMe is useful for people with **osteoarthritis** (page 328), reducing **pain** (page 338), stiffness, and swelling better than placebos and equal to drugs such as ibuprofen and naproxen.<sup>14, 15, 16, 17, 18, 19, 20, 21</sup>

Intravenous SAMe given to **fibromyalgia** (page 191) patients reduced pain and depression in two double-blind studies,<sup>22, 23</sup> but in a short (ten-day) trial no benefit was seen.<sup>24</sup> Oral SAMe was tested in one double-blind study and significant beneficial effects were noticed, such as reduced pain, fatigue, and stiffness, and improved mood.<sup>25</sup>

Oral and intravenous treatment with SAMe replenishes important substances in damaged livers and im-

proves the flow of bile.<sup>26, 27</sup> Preliminary research has indicated that SAMe may be helpful in a variety of liver conditions, including cholestasis, Gilbert's syndrome, alcoholic liver injury, and **cirrhosis** (page 290).<sup>28, 29, 30</sup> In alcoholic cirrhosis, damage to the liver prevents the natural formation of SAMe from the amino acid **methionine** (page 557). In a double-blind trial, people with cirrhosis of the liver due to alcoholism who took SAMe for two years had a 47% lower rate of death or need for liver transplantation, compared with those who received a placebo.<sup>31</sup> However, the improvement did not quite achieve statistical significance. In people with less severe cirrhosis, the results were more impressive and were also statistically significant.

Preliminary research also suggests oral SAMe may increase sperm activity in **infertile men** (page 304)<sup>32</sup> and may be helpful in the treatment of **migraine headaches** (page 316).<sup>33</sup> One double-blind study found injections of SAMe significantly more helpful than placebo injections for reducing the symptoms of post-concussion syndrome.<sup>34</sup>

### Where is it found?

SAMe is not abundant in the diet, though its precursor, the **amino acid** (page 465) **methionine** (page 557) is plentiful in many protein foods. It is not known whether increasing one's intake of methionine will increase the body's production of SAMe. Supplements of SAMe have been available in the U.S. since 1997.

**SAMe has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Liver cirrhosis</b> (page 290) <b>Osteoarthritis</b> (page 328)
★★☆	<b>Depression</b> (page 145) <b>Fibromyalgia</b> (page 191) <b>Hepatitis</b> (page 220) (for liver cholestasis) <b>Pregnancy and postpartum support</b> (page 363) (for cholestasis only)
★☆☆	<b>Bipolar disorder</b> (page 61) <b>Infertility (male)</b> (page 304) <b>Migraine headaches</b> (page 316) Post-concussion syndrome

### Who is likely to be deficient?

SAMe is normally produced in the liver from the **amino acid** (page 465) **methionine** (page 557) which

is abundant in most diets. **Folic acid** (page 520) and **vitamin B<sub>12</sub>** (page 601) are necessary for the synthesis of SAMe, and deficiencies of these vitamins results in low concentrations of SAMe in the central nervous system.<sup>35</sup> Low blood or central nervous system levels of SAMe have been detected in people with **cirrhosis of the liver** (page 290),<sup>36</sup> **coronary heart disease** (page 38),<sup>37</sup> **Alzheimer's disease** (page 19), and **depression** (page 145).<sup>38</sup>

### How much is usually taken?

Healthy people do not need to take this supplement. Researchers working with people suffering from a variety of conditions have been using these amounts of SAMe: **depression** (page 145), 1,600 mg per day; **osteoarthritis** (page 328), 800–1,200 mg per day; **fibromyalgia** (page 191), 800 mg per day; liver disorders, 1,200 mg per day; and **migraine** (page 316), 800 mg per day.

### Are there any side effects or interactions?

Clinical trials in thousands of people for up to two years have demonstrated that SAMe is very well tolerated, much better than the medications with which it has often been compared.<sup>39, 40</sup> Occasional **gastrointestinal upset** (page 195) may be experienced by some people. Researchers treating people with **bipolar disorder** (page 61) (manic depression) have reported that SAMe could cause them to switch from depression to a manic episode.<sup>41, 42</sup>

## SELENIUM

### What is it?

Selenium is an essential trace mineral.

Selenium activates an **antioxidant** (page 467) enzyme called glutathione peroxidase, which may help protect the body from **cancer** (page 87). Yeast-derived forms of selenium have induced "apoptosis" (programmed cell death) in cancer cells in test tubes and in animals.<sup>1, 2, 3</sup> A double-blind trial that included over 1,300 people found those given 200 mcg of yeast-based selenium per day for 4.5 years had a 50% drop in the cancer death rate compared with the placebo group.<sup>4</sup> In that same study, however, selenium supplementation was associated with a significant increase in the risk of developing one type of skin cancer (squamous cell carcinoma).<sup>5</sup> Another study found that men consuming the most dietary selenium (assessed indirectly by mea-

suring toenail selenium levels) developed 65% fewer cases of advanced **prostate cancer** (page 371) than did men with the lowest levels of selenium intake.<sup>6</sup>

Selenium is also essential for healthy **immune functioning** (page 371). Selenium supplementation has reduced the incidence of viral **hepatitis** (page 220) in selenium-deficient populations, presumably by enhancing immune function.<sup>7</sup> Even in a non-deficient population of elderly people, selenium supplementation has been found to stimulate the activity of white blood cells—primary components of the immune system.<sup>8</sup> Selenium is also needed to activate thyroid hormones.

In a placebo-controlled study, supplementation with 200 mcg per day of selenium for three months reduced anti-thyroid antibody levels (indicating a reduction in disease activity) in people with autoimmune thyroiditis (inflammation of the thyroid gland).<sup>9</sup>

In a double-blind trial, selenium supplementation of **infertile men** (page 305) improved the motility of sperm cells and increased the chance of conception.<sup>10</sup>

### Where is it found?

Brazil nuts are the best source of selenium. Yeast, whole grains, and seafood are also good sources. Animal studies have found that selenium from yeast is better absorbed than selenium in the form of selenite.<sup>11</sup>

**Selenium has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Asthma</b> (page 32) <b>Atherosclerosis</b> (page 38) <b>Colon cancer</b> (page 134) (reduces risk) <b>Depression</b> (page 145) <b>Dermatitis herpetiformis</b> (page 151) <b>Heart attack</b> (page 212) <b>HIV support</b> (page 239) <b>Immune function</b> (page 255) (for elderly people) <b>Infections</b> (page 265) (to prevent hospital-acquired infections in very low birth weight infants) <b>Infertility (male)</b> (page 305) <b>Lung cancer</b> (page 298) (reduces risk) <b>Lymphedema</b> (page 180) <b>Pancreatic insufficiency</b> (page 341) <b>Phenylketonuria</b> (page 354) (if deficient) <b>Prostate cancer</b> (page 371) (reduces risk) <b>Rheumatoid arthritis</b> (page 387) <b>Thyroiditis</b> (autoimmune)

**Retinopathy** (page 385) (combined with **vitamin A** [page 595], **vitamin C** [page 604], and **vitamin E** [page 609])

### Who is likely to be deficient?

While most people probably don't take in enough selenium, gross deficiencies are rare in Western countries. Soils in some areas are selenium-deficient and people who eat foods grown primarily on selenium-poor soils are at risk for deficiency. People with **AIDS** (page 239) have been reported to be depleted in selenium.<sup>12</sup> Similarly, limited research has reported an association between **heart disease** (page 98) and depleted levels of selenium.<sup>13</sup> People who are deficient in selenium have an increased risk of developing certain types of **rheumatoid arthritis** (page 387).<sup>14</sup>

### How much is usually taken?

While the Recommended Dietary Allowance for most adults is 55 mcg per day, an adult intake of 100–200 mcg of selenium per day is recommended by many doctors.

### Are there any side effects or interactions?

Selenium is safe at the level people typically supplement (100–200 mcg); however, taking more than 900 mcg of selenium per day has been reported to cause adverse effects in some people.<sup>15</sup> Selenium toxicity can result in loss of fingernails, skin rash, and changes in the nervous system. In the presence of **iodine** (page 538)-deficiency-induced **goiter** (page 206), selenium supplementation has been reported to exacerbate low thyroid function.<sup>16</sup> Although most research suggests that selenium prevents cancer, one study found an increased risk of a type of skin cancer (squamous cell carcinoma)

in people taking selenium supplements.<sup>17</sup> The National Academy of Sciences recommends that selenium intake not exceed 400 mcg per day, unless the higher intake is monitored by a healthcare professional.<sup>18</sup>

Selenium enhances the **antioxidant** (page 467) effect of **vitamin E** (page 609).

## SILICA HYDRIDE

### What is it?

Silica hydride is a colloidal mineral compound containing silicon, oxygen, and hydrogen. According to the developers of this supplement, silica hydride contains a large number of loosely bound electrons that are available to help neutralize potentially dangerous free radicals.<sup>1, 2</sup> Test tube studies have demonstrated that silica hydride does neutralize free radicals and preserves the health of cells exposed to these radicals. However, whether silica hydride can be absorbed from the gastrointestinal tract and whether it will affect the health of animals or humans has not been adequately tested.

A preliminary study attempted to measure health-promoting properties of silica hydride with a computerized analysis of blood, urine, and saliva samples called Biological Terrain Assessment (BTA). BTA testing indicated some potentially positive effects of silica hydride in healthy people, but no effects in people with diagnosed health problems.<sup>3</sup> BTA has not been proven to be a reliable method for evaluating health or disease,<sup>4</sup> so even this marginally promising report should be regarded tentatively.

Another claim made is that the electrons in silica hydride can help promote the body's production of the energy-containing substance adenosine triphosphate (ATP). While test tube studies have demonstrated that some preliminary steps in energy production are facilitated by silica hydride,<sup>5</sup> no evidence exists that this will increase ATP production in the body.

### Where is it found?

Since silica hydride is not essential, a recommended intake has not been established. Whether it is present in food or water is unknown. Supplements contain 200 to 250 mg per capsule.

### Who is likely to be deficient?

Silica hydride is not an essential nutrient, so no deficiencies are possible.

### How much is usually taken?

Since silica hydride is not essential, a recommended intake has not been established. Whether it is present in food or water is unknown. Supplements contain 200 to 250 mg per capsule.

### Are there any side effects or interactions?

Due to the lack of published scientific research on silica hydride in animals or humans, side effects and interactions are unknown.

## SILICON

### What is it?

Silicon is a trace mineral.

The functions of silicon are not well understood, although silicon probably plays a role in making and maintaining connective tissue. Silicon is present in areas of bone that are undergoing mineralization, which indicates this mineral might be important for normal bone function; however, evidence for this has not been confirmed in humans.<sup>1</sup>

### Where is it found?

Good dietary sources for silicon include whole-grain breads and cereals, root vegetables, and beer. A form of silicon called silicates is added to some processed foods.

**Silicon has been used in connection with the following condition** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Osteoporosis (page 333) Sprains and strains (page 412)

### Who is likely to be deficient?

Silicon is not an essential mineral. Deficiencies have not been reported.

### How much is usually taken?

Because silicon has not been established as essential, a recommended intake has not been established. The average diet is estimated to provide 5–20 mg of silicon per day—an amount that appears adequate. When used as a supplement, common amounts range from 1 to 2 mg per day.

### Are there any side effects or interactions?

A high dietary intake of silicon is not associated with any toxic effects. Inhalation of large amounts of silicon (in an industrial setting) can cause the respiratory disease silicosis.

## SOY

### What is it?

Soy, a staple food in many Asian countries, contains valuable constituents, including protein, isoflavones, saponins, and phytosterols. Soy protein provides essential **amino acids** (page 465). When eaten with rice, soy provides protein comparable with that found in animal products. Soy is low in fat and cholesterol-free.

The isoflavones in soy, primarily genistein and daidzein, have been well researched by scientists for their **antioxidant** (page 467) and phytoestrogenic properties.<sup>1</sup> Saponins enhance **immune function** (page 255) and bind to cholesterol to limit its absorption in the intestine. Phytosterols and other components of soy have been reported to lower **cholesterol levels** (page 223).

The soy isoflavone genistein has been reported to inhibit angiogenesis,<sup>2</sup> the growth of new blood vessels that, when abnormal, can contribute to the development of **cancer** (page 87). Soy isoflavones have also been shown to inhibit 5 alpha-reductase,<sup>3</sup> the **enzyme** (page 506) that activates testosterone in the prostate gland and other tissues. 5 Alpha-reductase inhibition represents a potentially effective therapeutic approach to **benign prostate enlargement** (page 58) and male pattern baldness.

Isoflavones may reduce the risk of hormone-dependent cancers, such as **breast** (page 65) and **prostate cancer** (page 371), as well as other cancers. One study of soy research found that 65% of 26 animal-based cancer studies showed a protective effect of soy or soy isoflavones.<sup>4</sup> Human research also suggests a protective role of soy against cancer,<sup>5,6</sup> but the data are currently insufficient to form any solid conclusions.<sup>7</sup>

A review of 38 different studies revealed that soy consumption reduced **cholesterol** (page 223) levels in 89% of the studies. A meta-analysis of these studies indicated that eating soy resulted, on average, in a cholesterol reduction of 23 mg per deciliter.<sup>8</sup> Exactly how soy lowers cholesterol remains in debate,<sup>9</sup> though isoflavones appear to be one key component.<sup>10</sup>

The mild estrogenic activity of soy isoflavones may ease **menopause** (page 311) symptoms for some women, without creating estrogen-related problems. In one double-blind trial, supplementation with 60 grams of soy protein per day for 12 weeks led to a 45% decrease in the number of hot flashes, compared with a 30% reduction in the placebo group, a statistically significant difference.<sup>11</sup> In addition, soy may help regulate hormone levels in premenopausal women.<sup>12</sup>

Soy may also be beneficial in preventing **osteoporosis** (page 333). Isoflavones from soy have protected against bone loss in animal studies.<sup>13</sup> In a double-blind study of postmenopausal women, supplementation with 40 grams of soy protein powder per day (containing 90 mg of isoflavones per day) protected against bone mineral loss in the spine.<sup>14</sup> Although the use of soy in the prevention of osteoporosis looks hopeful, no long-term human studies have examined the effects of soy or soy-derived isoflavones on bone density or fracture risk.

### Where is it found?

Relatively large amounts of isoflavones are present in whole soybeans, roasted soy nuts, tofu, tempeh, soy milk, meat substitutes, soy flour, and some soy protein isolates. In addition, the isoflavones present in soy are available as supplements, in capsules or tablets.

**Soy has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>High cholesterol</b> (page 223) <b>Menopause</b> (page 311)
★★☆	<b>High blood pressure</b> (page 246) <b>Osteoporosis</b> (page 333)
★☆☆	<b>Vaginitis</b> (page 438)

### Who is likely to be deficient?

Although deficiencies do not occur, people who do not consume soy foods will not gain the benefits of soy.

### How much is usually taken?

The ideal intake of soy is not known. Researchers suggest the equivalent of one serving of soy foods per day supports good health, and the benefits increase as soy intake increases.<sup>15</sup> Societies in which large amounts of

soy are consumed ingest between 50 and 100 mg per day of soy isoflavones. The **cholesterol** (page 223)-lowering effects of soy have been observed at amounts as low as 20 grams of soy protein per day, if it replaces animal protein in the diet.<sup>16</sup>

### Are there any side effects or interactions?

Soy products and cooked soybeans are safe at a wide range of intakes. However, a small percentage of people have **allergies** (page 14) to soybeans and thus should avoid soy products.

Soy isoflavones have been reported to reduce thyroid function in some people.<sup>17</sup> A preliminary trial of soy supplementation among healthy Japanese, found that 30 grams (about one ounce) per day of soybeans for three months, led to a slight reduction in the hormone that stimulates the thyroid gland.<sup>18</sup> Some participants complained of malaise, **constipation** (page 137), sleepiness, and even **goiter** (page 206). These symptoms resolved within a month of discontinuing soy supplements. However, a variety of soy products have been shown to either cause an *increase* in thyroid function<sup>19</sup> or produce no change in thyroid function.<sup>20</sup> The clinical importance of interactions between soy and thyroid function remains unclear. However, in infants with congenital **hypothyroidism** (page 252), soy formula must not be added, nor removed from the diet, without consultation with a physician, because ingestion of soy may interfere with the absorption of thyroid medication.<sup>21</sup>

Most research, including animal studies, report **anti-cancer** (page 87) effects of soy extracts,<sup>22</sup> though occasional animal studies have reported cancer-enhancing effects.<sup>23</sup> The findings of several recent studies suggest that consuming soy might, under some circumstances, *increase* the risk of **breast cancer** (page 65). When ovaries have been removed from animals—a situation related to the condition of women who have had a total hysterectomy—dietary genistein has been reported to *increase* the proliferation of breast cancer cells.<sup>24</sup> When pregnant rats were given genistein injections, their female offspring were reported to be at *greater* risk of breast cancer.<sup>25</sup> Although **premenopausal** (page 311) women have shown decreases in estrogen levels in response to soy,<sup>26, 27</sup> pro-estrogenic effects have also been reported.<sup>28</sup> When pre-menopausal women were given soy isoflavones, an increase in breast secretions resulted—an effect thought to *elevate* the risk of breast

cancer.<sup>29</sup> In yet another trial, healthy breast cells from women previously given soy supplements containing isoflavones showed an *increase* in proliferation rates—an effect that might also increase the risk of breast cancer.<sup>30</sup>

Of 154 healthy postmenopausal women who received 150 mg of soy isoflavones per day for five years, 3.9% developed an abnormal proliferation of the tissue that lines the uterus (endometrial hyperplasia). In contrast, none of 144 women who received a placebo developed uterine hyperplasia.<sup>31</sup> Although no case of uterine cancer was diagnosed during the study, endometrial hyperplasia is a potential forerunner of uterine cancer. The amount of isoflavones used in this study is two to three times as much as that used in many other studies. Nevertheless, the possibility exists that long-term use of isoflavones could cause uterine hyperplasia, and women taking isoflavones should be monitored appropriately by their doctor.

Soy contains a compound called phytic acid, which can interfere with mineral absorption.

## SPLEEN EXTRACTS

### What are they?

Spleen extracts are extracts derived from the spleens of beef (bovine) sources. The spleen is a fist-sized, spongy, dark purple organ that lies in the upper left abdomen behind the lower ribs. Weighing about 7 ounces, the spleen is the largest mass of lymphatic tissue in the body. The spleen produces white blood cells, engulfs and destroys bacteria and cellular debris, and destroys worn-out red blood cells and platelets.

A series of case reports in the early 1930s demonstrated that orally administered bovine spleen extracts were able to raise white-blood-cell counts in individuals with extremely low counts, as well as to benefit patients with malaria and typhoid fever.<sup>1, 2, 3</sup> However, there does not appear to be any more recent studies with these sorts of preparations. Most of the recent research with spleen extracts has focused on the use of injectable preparations or isolated spleen proteins, such as tuftsin and splenopentin.<sup>4, 5, 6, 7</sup> Although these preparations have been shown to enhance **immune function** (page 255), it is not known whether the same benefits can be obtained with oral preparations.

**Where are they found?**

Spleen extracts are available as nutritional supplements in capsules and tablets.

**Spleen extracts have been used in connection with the following condition** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Cancer chemotherapy, adverse effects
★☆☆	Low white-blood-cell count

**Who is likely to be deficient?**

As spleen extract is not an essential nutrient, no deficiency state exists.

**How much is usually taken?**

The recommended amount depends on the concentration, method of preparation, and quality of the extract. Follow the manufacturer's recommendation on the label.

**Are there any side effects or interactions?**

No side effects or adverse effects have been reported with the use of oral spleen preparations.

## STRONTIUM

**What is it?**

Strontium is a mineral that is not classified as essential for the human body.

There is research that strontium has been shown to promote strong, **osteoporosis** (page 333)-resistant bones,<sup>1</sup> lessen the risk of dental cavities,<sup>2</sup> and reduce the **pain** (page 338) of bone lesions that occasionally develop in association with certain **cancers** (page 87).<sup>3</sup> The type of strontium used as a supplement is not the radioactive type.

**Where is it found?**

Strontium is widely distributed throughout nature. Strontium levels in the soil determine how much strontium will be in the foods grown in particular areas. Areas with strontium-rich soils also tend to have higher levels of strontium in the drinking water.

**Strontium has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Dental cavities (page 431) Osteoporosis (page 333)

**Who is likely to be deficient?**

Strontium is not an essential mineral, so deficiencies are not seen with this mineral.

**How much is usually taken?**

No recommended intake levels have been established for strontium, since it is not considered essential for humans. However, preliminary research in humans suggests that 600–1,700 mg of strontium, taken as a supplement in the form of strontium salts, may increase bone mass in the vertebrae of people with **osteoporosis** (page 333).<sup>4</sup>

**Are there any side effects or interactions?**

No consistent toxicities from strontium supplements have been reported.

## SULFORAPHANE

**What is it?**

Sulforaphane is a compound that was identified in broccoli sprouts by scientists at the Johns Hopkins University School of Medicine in Baltimore, MD.<sup>1</sup>

These researchers were investigating the **anticancer** (page 87) compounds present in broccoli when they discovered that broccoli sprouts contain anywhere from 30 to 50 times the concentration of protective chemicals that are found in mature broccoli plants.<sup>2</sup> Sulforaphane is one of a class of chemicals called isothiocyanates. Sulforaphane and other isothiocyanates are **antioxidants** (page 467) and potent stimulators of natural detoxifying enzymes in the body. These compounds are believed to be responsible for the lowered risk of cancer that is associated with the consumption of broccoli and other cruciferous vegetables, such as cauliflower, cabbage, and kale.<sup>3, 4, 5, 6, 7, 8, 9</sup>

Feeding sulforaphane-rich broccoli-sprout extracts to laboratory rats exposed to a carcinogen dramatically reduced the frequency, size, and number of the rats' tu-

mors.<sup>10, 11, 12</sup> Human studies with sulforaphane and other cruciferous-vegetable components have shown that these compounds stimulate the body's production of detoxification enzymes and exert antioxidant effects.<sup>13, 14, 15</sup>

Preliminary studies suggest that in order to cut the risk of cancer in half, the average person would need to eat about two pounds of broccoli or similar vegetables per week. Since the concentration of sulforaphane is much higher in broccoli sprouts than in mature broccoli, the same reduction in risk theoretically might be had with a weekly intake of just over an ounce of sprouts.

### Where is it found?

Sulforaphane is found in highest concentrations in broccoli sprouts, but it is also found in mature broccoli and other cruciferous vegetables, such as cauliflower, cabbage, and kale.

**Sulforaphane has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Cancer (page 87) (risk reduction)

### Who is likely to be deficient?

Sulforaphane is not an essential nutrient, and thus no deficiency state exists.

### How much is usually taken?

The optimal level of intake is not known, but some doctors recommend 200 to 400 mcg of sulforaphane daily from broccoli-sprout extracts.

### Are there any side effects or interactions?

No side effects or drug interactions have been reported, although sulforaphane and dietary consumption of cruciferous vegetables does interact with drug detoxifying enzymes (page 506).<sup>16</sup> People taking prescription drugs should therefore consult a doctor before taking sulforaphane or broccoli-sprout extracts.

## SULFUR

### What is it?

Sulfur is a mineral needed for the manufacture of many proteins, including those forming hair, muscles,

and skin. Sulfur contributes to fat digestion and absorption, because it is needed to make bile acids. Sulfur is also a constituent of bones, teeth, and collagen (the protein in connective tissue). As a component of insulin, sulfur is needed to regulate blood sugar. Sulfur is present in **methylsulfonylmethane (MSM)** (page 558), a naturally-occurring substance available as a supplement.

### Where is it found?

Most dietary sulfur is consumed as part of certain **amino acids** (page 465) in protein-rich foods. Meat and poultry, organ meats, fish, eggs, beans, and dairy products are all good sources of sulfur-containing amino acids. Sulfur also occurs in **garlic** (page 679) and onions and may be partially responsible for the health benefits associated with these items.<sup>1</sup>

Most of the body's sulfur is found in the sulfur-containing amino acids **methionine** (page 557), cysteine, and **cysteine** (page 502). **Vitamin B<sub>1</sub>** (page 597), **biotin** (page 473), and **pantothenic acid** (page 568) contain small amounts of sulfur.

### Who is likely to be deficient?

Deficiencies of sulfur have not been documented, although a protein-deficient diet could theoretically lead to a deficiency of sulfur. Low levels of cystine, and therefore possibly sulfur, were reported many years ago in people with arthritis, but this association is far from proven.<sup>2</sup>

### How much is usually taken?

No recommended intake levels have been established for sulfur. Since most Western diets are high in protein, the majority of diets probably supply enough sulfur.

### Are there any side effects or interactions?

No side effects have been reported with the use of sulfur.

## TAURINE

### What is it?

Taurine is an **amino acid** (page 465)-like compound and a component of bile acids, which are used to help absorb fats and fat-soluble **vitamins** (page 559). Taurine also helps regulate the heart beat, maintain cell membrane stability, and prevent brain cell over-activity.

### Where is it found?

Taurine is found mostly in meat and fish. Except for infants, the human body is able to make taurine from **cysteine** (page 502)—another **amino acid** (page 465).

### Taurine has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Congestive heart failure</b> (page 134)
★★☆	<b>Cystic fibrosis</b> (page 143) <b>Iron-deficiency anemia</b> (page 278) Liver support <b>Pre- and post-surgery health</b> (page 357)
★☆☆	<b>Cardiomyopathy</b> (page 95) <b>Diabetes</b> (page 152) <b>Epilepsy</b> (page 183) <b>High blood pressure</b> (page 246)

### Who is likely to be deficient?

Most people, including vegans (vegetarians who eat no dairy or eggs), do not need taurine supplements. While infants require taurine, the amount in either human milk or formula is adequate. People with **diabetes** (page 152) have been reported to have lower blood levels of taurine than non-diabetics.<sup>1</sup>

### How much is usually taken?

For the treatment of various medical conditions, doctors typically recommend 1.5 grams to as much as 6 grams or more per day.

### Are there any side effects or interactions?

Taurine has not been reported to cause any severe adverse effects.

## THYMUS EXTRACTS

### What are they?

Thymus extracts are extracts derived from the thymus glands usually of young calves (bovine). The thymus is one of our major **immune system** (page 255) glands. It is composed of two soft pinkish-gray lobes lying in bib-like fashion just below the thyroid gland and above the heart. To a large extent, the health of the thymus determines the health of the immune system. The thymus is responsible for many immune system functions, includ-

ing the production of T lymphocytes, a type of white blood cell responsible for “cell-mediated immunity.” Cell-mediated immunity refers to immune mechanisms not controlled or mediated by antibodies. Cell-mediated immunity is extremely important in the resistance to infection by certain bacteria, yeast (including *Candida albicans*), fungi, **parasites** (page 343), and viruses (including **herpes simplex** [page 119], Epstein-Barr, and the viruses that cause **hepatitis** [page 220]). Cell-mediated immunity is also critical in protecting against the development of **cancer** (page 87), **allergies** (page 14), and autoimmune disorders such as **rheumatoid arthritis** (page 387). The thymus gland also releases several hormones, such as thymosin, thymopoietin, and serum thymic factor, that regulate many immune functions.

The oral calf thymus extract that has been studied scientifically is specially prepared to concentrate small protein-like molecules (polypeptides). This extract (known as Thymomodulin) has been shown effective in preventing recurrent upper respiratory tract infections.

Preliminary studies suggest that Thymomodulin may also be helpful in (1) improving one of the T-cell defects in patients with human immunodeficiency virus infection (**HIV** [page 239]—the virus that causes AIDS); (2) treating acute and chronic **hepatitis** (page 220) B infections; (3) restoring the number of peripheral white blood cells in **cancer** (page 87) patients undergoing chemotherapy or radiation; and (4) relieving **allergies** (page 14), including **asthma** (page 32), **hay fever** (page 211), and food allergies, in children.<sup>1, 2</sup> The effectiveness of Thymomodulin in these conditions may be the result of improved thymus gland activity, or it may be due to the presence of hormones or other biologically active substances in the extract.

The ability of Thymomodulin to improve **immune function** (page 255) and reduce the number of recurrent **infections** (page 265) has been shown in double-blind studies of children and adults with a history of recurrent respiratory-tract infections.<sup>3, 4, 5, 6, 7</sup> Thymomodulin has also been shown in a double-blind study to improve immune function in cases of exercise-induced immune suppression. In addition, preliminary studies have shown the extract to improve immune function in people with **diabetes** (page 152) and in elderly people.<sup>8, 9, 10, 11</sup> (Extreme **exercise** (page 43), diabetes, and aging are all associated with suppression of immune function.)

Preliminary studies in patients with acute or chronic hepatitis suggest that supplementation with Thymomodulin may be helpful.<sup>12, 13</sup> However, additional studies are needed to confirm these findings.

In a preliminary study in patients with early HIV infection, Thymomodulin improved several measures of immune function, including an increase in the number of T-helper cells, one of the goals in the treatment of HIV infection.<sup>14</sup> Thymomodulin (given orally or by injection) has been used in **cancer** (page 87) patients to counteract the decline in white-blood-cell levels that can result from chemotherapy or radiation.<sup>15, 16, 17, 18, 19, 20</sup> In test tube studies, Thymomodulin and other thymus extracts have been shown to exert a number of effects on white blood cells (e.g., increasing both the bone marrow production and functional activity of white blood cells).<sup>21, 22</sup> However, it is not yet known if this effect can be achieved with the use of oral thymus extracts.

The oral administration of Thymomodulin has been shown in preliminary and double-blind clinical trials to improve the symptoms and course of **hay fever** (page 211), allergic **rhinitis** (page 407), **asthma** (page 32), **eczema** (page 177), and food **allergies** (page 14) (in conjunction with an allergy elimination diet).<sup>23, 24, 25, 26, 27, 28, 29, 30</sup> Presumably, this clinical improvement results from restoring proper control over **immune function** (page 255).

Thymomodulin given by injection has also been shown to be helpful in the treatment of diseases of the heart muscle (idiopathic myocarditis and idiopathic dilated **cardiomyopathy** [page 95]).<sup>31, 32</sup> It is not known whether oral thymus extracts can achieve these same benefits.

#### **Where are they found?**

Thymus extracts (from bovine sources) are found in capsules and tablets as a dietary supplement. Thymomodulin is not available in the United States, and it is unknown whether any of the thymus extracts that are available have the same effects as Thymomodulin.

#### **Thymus extracts have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Bronchitis</b> (page 80)
★★☆	<b>Allergies</b> (page 14) <b>Hay fever</b> (page 211) <b>Hepatitis</b> (page 220) <b>Immune function</b> (page 255) Recurrent upper respiratory tract infections
★☆☆	<b>Asthma</b> (page 32) <b>HIV infection</b> (page 239)

#### **Who is likely to be deficient?**

Since it is not an essential nutrient, no deficiency state exists.

#### **How much is usually taken?**

A number of different thymus preparations are commercially available. However, whether any of them have the same effects as Thymomodulin, which is not available in the United States, is still unknown. The recommended amount of thymus extract varies according to the type of preparation.

#### **Are there any side effects or interactions?**

No side effects or adverse reactions have been reported with the use of thymus preparations.

## THYROID EXTRACTS

#### **What are they?**

Thyroid extracts are thyroid extracts derived from the thyroid glands of usually bovine (beef) sources.

The hormones of the thyroid gland regulate metabolism in every cell of the body. The medical treatment of underactive thyroid (**hypothyroidism** [page 252]) usually involves a prescription of synthetic thyroid hormones (thyroxine and/or triiodothyronine) or thyroid extract (desiccated thyroid). The difference between prescription thyroid extract and the thyroid extracts sold as nutritional supplements is the latter are required by the U.S. Food and Drug Administration to be free of the known active thyroid hormones (thyroxine and triiodothyronine). The use of hormone-free thyroid preparations has not been evaluated in scientific studies, but some doctors believe these products may provide nutritional support to the thyroid gland or contain other compounds with possible hormonal activity.

#### **Where are they found?**

Thyroid extracts are available as nutritional supplements in capsules and tablets.

#### **Thyroid extracts have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Hypothyroidism</b> (page 252)

### Who is likely to be deficient?

As thyroid extract is not an essential nutrient, therefore, no deficiency state exists.

### How much is usually taken?

The recommended intake depends on the concentration, method of preparation, and quality of the thyroid extract. Follow the manufacturer's recommendation on the label.

### Are there any side effects or interactions?

No side effects or adverse reactions have been reported. However, people taking prescription thyroid hormones should consult their doctor before using non-prescription thyroid extracts.

## TOCOTRIENOLS

### What are they?

Tocotrienols are members of the **vitamin E** (page 609) family. Like vitamin E, tocotrienols are potent **antioxidants** (page 467) against lipid peroxidation (the damaging of fats by oxidation).<sup>1,2</sup>

Human studies indicate that, in addition to their antioxidant activity, tocotrienols have other important functions, especially in maintaining a healthy cardiovascular system.<sup>3</sup> Test tube and animal studies indicate a possible role for tocotrienols in protecting against **cancer** (page 87) (particularly **breast** [page 65] and skin cancer).

Like vitamin E, tocotrienols may offer protection against hardening of the arteries (**atherosclerosis** [page 38]) by preventing oxidative damage to **LDL cholesterol** (page 223) (oxidation of LDL cholesterol is believed to be one of the triggering factors for atherosclerosis).<sup>4</sup> In a double-blind study in patients with severe atherosclerosis of the carotid artery—the main artery supplying blood to the head—tocotrienol administration (200 mg per day) reduced the level of lipid peroxides in the blood. Moreover, in a small sample of patients receiving tocotrienols for 12 months, the size of atherosclerotic plaques became smaller. In contrast, none of the patients receiving the placebo showed an improvement in their atherosclerosis.<sup>5</sup>

Although tocotrienols inhibited **cholesterol** (page 223) synthesis in test tube studies,<sup>6,7</sup> human studies have produced conflicting results. In a preliminary

study, supplementation with 200 mg of gamma-tocotrienol reduced total cholesterol levels significantly—by 13% in four weeks.<sup>8</sup> In a double-blind study, 200 mg of tocotrienols per day produced a significant 15% drop in total cholesterol and an 8% reduction in LDL levels. There were no changes in these levels in the placebo group.<sup>9</sup> However, another double-blind study showed that 200 mg of tocotrienols per day failed to lower cholesterol levels.<sup>10</sup> In the most recent double-blind study, a group of men with slightly elevated cholesterol levels given 140 mg of tocotrienols and about 120 IU mg of **vitamin E** (page 609) daily demonstrated no changes in total cholesterol, LDL cholesterol, or HDL cholesterol levels after four weeks of supplementation.<sup>11</sup>

Test tube studies indicate that tocotrienols exert some **anticancer** (page 87) effects, especially against skin and **breast cancer** (page 65).<sup>12, 13, 14, 15, 16</sup> These results still need confirmation in human studies, however.

### Where are they found?

Tocotrienols are found primarily in the oil fraction of rice bran, palm fruit, barley, and wheat germ. Supplemental sources of tocotrienols are derived from rice bran oil and palm oil distillates. Tocotrienol supplements are available in capsules and tablets.

**Tocotrienols have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Atherosclerosis</b> (page 38)
★★☆	<b>High Cholesterol</b> (page 223)
★☆☆	<b>Stroke</b> (page 419)

### Who is likely to be deficient?

As it is not an essential nutrient, no deficiency state exists.

### How much is usually taken?

The typical recommendation is 140 to 360 mg per day. Most studies have used 200 mg daily.

### Are there any side effects or interactions?

No significant adverse effects have been reported with tocotrienols.<sup>17</sup>

## VANADIUM

### What is it?

Vanadium is an ultra-trace mineral found in the human diet and the human body. It is essential for some animals. Deficiency symptoms in these animals include growth retardation, bone deformities, and infertility. However, vanadium has not been proven to be an essential mineral for humans.

Vanadium may play a role in building bones and teeth.

Vanadyl sulfate, a form of this mineral, may improve glucose control in people with type 2 (adult-onset or non-insulin-dependent) **diabetes** (page 152) mellitus, according to a study of eight people with diabetes who supplemented with 100 mg of the mineral daily for four weeks.<sup>1</sup> However, the researchers of this study caution that the long-term safety of such large amounts of vanadium remains unknown. Many doctors expect future research to show that amounts this high will likely prove to be unsafe. Moreover, in a preliminary report, vanadium did not help people with type 1 (childhood-onset or insulin-dependent) diabetes.<sup>2</sup>

### Where is it found?

Vanadium is found in very small amounts in a wide variety of foods, including seafood, cereals, mushrooms, parsley, corn, soy, and gelatin.

### Vanadium has been used in connection with the following condition

Rating	Health Concerns
★☆☆	<b>Diabetes</b> (page 152)

### Who is likely to be deficient?

Deficiencies of vanadium have not been reported in humans, and it is not known whether this mineral is essential for humans.

### How much is usually taken?

As yet, research indicates that most people would not benefit from vanadium supplementation. Optimal intake of vanadium is unknown. If vanadium turns out to be essential for humans, the estimated requirement

would probably be less than 10 mcg per day. An average diet provides 15–30 mcg per day.

### Are there any side effects or interactions?

Information about vanadium toxicity is limited. Workers exposed to vanadium dust can develop toxic effects. High blood levels have been linked to **manic-depressive** (page 61) mental disorders, but the meaning of this remains uncertain.<sup>3</sup> Vanadium sometimes inhibits, but at other times stimulates, **cancer** (page 87) growth in animals. However, the effect in humans remains unknown.<sup>4</sup>

Vanadium is not known to interact with other nutrients.

## VINPOCETINE

### What is it?

Vinpocetine is a chemical substance synthesized from vincamine, a natural constituent found in the leaves of *Vinca minor* (lesser periwinkle).

Vinpocetine appears to have antioxidant,<sup>1</sup> blood flow enhancing,<sup>2, 3, 4, 5</sup> and other effects that may be beneficial to brain function.<sup>6, 7, 8, 9, 10</sup> Research, primarily in Europe, has investigated these possible benefits in people with memory disorders (dementias) and people who have suffered strokes.

### Where is it found?

Vinpocetine is synthesized from vincamine, a constituent of the leaves of *Vinca minor* (lesser periwinkle).

### Vinpocetine has been used in connection with the following condition (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Age-related cognitive decline</b> (page 8)
★★☆	<b>Stroke</b> (page 419) (intravenous vinpocetine only) <b>Vertigo</b> (page 441)
★☆☆	<b>Alzheimer's disease</b> (page 19) Memory <b>Retinopathy</b> (page 385) Urinary incontinence

### Who is likely to be deficient?

Vinpocetine is not an essential nutrient, so no deficiencies are possible.

### How much is usually taken?

Research has typically used 30 to 60 mg per day of vinpocetine. Taking vinpocetine with food appears to dramatically improve its absorption.<sup>11</sup>

### Are there any side effects or interactions?

Studies on vinpocetine report no serious side effects with amounts up to 60 mg per day.<sup>12</sup> Vinpocetine has blood-thinning effects,<sup>13</sup> which suggests that people with bleeding disorders or who are taking anticoagulant or other blood-thinning medications should consult a doctor before taking vinpocetine. However, one study found no such interaction between vinpocetine and the anticoagulant drug warfarin.<sup>14</sup>

## VITAMIN A

See also: **Beta-carotene** (page 469)

### What is it?

Vitamin A is a fat-soluble vitamin with four major functions in the body: (1) It helps cells reproduce normally—a process called differentiation (cells that have not properly differentiated are more likely to undergo pre-cancerous changes). (2) It is required for vision; vitamin A maintains healthy cells in various structures of the eye and is required for the transduction of light into nerve signals in the retina. (3) It is required for normal growth and development of the embryo and fetus, influencing genes that determine the sequential development of organs in embryonic development. (4) It may be required for normal reproductive function, with influences on the function and development of sperm, ovaries and placenta.

For some people, water-soluble forms of vitamin A supplements appear to be better absorbed than fat-soluble vitamin A.

### Where is it found?

Liver, dairy products, and **cod liver oil** (page 514) are good sources of vitamin A. Vitamin A is also available in supplement form.

**Vitamin A has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Anemia</b> (page 25) (for deficiency) <b>Childhood diseases</b> (page 105) <b>Cystic fibrosis</b> (page 143) <b>Infection</b> (page 265) <b>Leukoplakia</b> (page 289) <b>Measles</b> (page 307) (for deficiency) <b>Night blindness</b> (page 326)
★★☆	<b>Bronchitis</b> (page 80) <b>Celiac disease</b> (page 102) (for deficiency only) <b>Heart attack</b> (page 212) <b>Immune function</b> (page 255) <b>Iron-deficiency anemia</b> (page 278) (as an adjunct to supplemental iron) <b>Measles</b> (page 307) (for severe cases) <b>Menorrhagia</b> (page 314) (heavy menstruation) <b>Peptic ulcer</b> (page 349) <b>Retinitis pigmentosa</b> <b>Sprains and strains</b> (page 412) (for deficiency only) <b>Wound healing</b> (page 319)
★☆☆	<b>Acne</b> (page 4) <b>Alcohol withdrawal support</b> (page 12) <b>Conjunctivitis/blepharitis</b> (page 136) <b>Crohn's disease</b> (page 141) <b>Diabetic retinopathy</b> (page 385) (in combination with <b>selenium</b> [page 584], <b>vitamin C</b> [page 604], and <b>vitamin E</b> [page 609]) <b>Diarrhea</b> (page 152) <b>Gastritis</b> (page 195) <b>Goiter</b> (page 206) <b>HIV support</b> (page 239) <b>Hypothyroidism</b> (page 252) <b>Lung cancer</b> (page 298) <b>Pap smear (abnormal)</b> (page 3) <b>Pre- and post-surgery health</b> (page 357) <b>Premenstrual syndrome</b> (page 368) (see dosage warnings) <b>Retinopathy</b> (page 385) (in combination with <b>selenium</b> [page 584], <b>vitamin C</b> [page 604], and <b>vitamin E</b> [page 609]) <b>Sickle cell anemia</b> (page 403) <b>Urinary tract infection</b> (page 436) <b>Vaginitis</b> (page 438)

### Who is likely to be deficient?

People who limit their consumption of liver, dairy foods, and **beta-carotene** (page 469)-containing vegetables can develop a vitamin A deficiency. Extremely low birth weight babies (2.2 pounds or less) are at high

risk of being born with a deficiency, and vitamin A shots given to these infants have been reported in double-blind research to reduce the risk of lung disease.<sup>1</sup> The earliest deficiency sign is poor **night vision** (page 326). Deficiency symptoms can also include dry skin, increased risk of **infections** (page 265), and metaplasia (a precancerous condition). Severe deficiencies causing blindness are extremely rare in Western societies.

Less severe deficiencies are more likely to occur with a variety of conditions causing **malabsorption** (page 304). A high incidence of vitamin A deficiency in people infected with **HIV** (page 239) has also been reported. People with **hypothyroidism** (page 252) have an impaired ability to convert **beta-carotene** (page 469) to vitamin A.<sup>2,3</sup> For this reason, some doctors suggest taking supplemental vitamin A (perhaps 5,000–10,000 IU per day) if they are not consuming adequate amounts in their diet.

Very old people with type 2 **diabetes** (page 152) have shown a significant age-related decline in blood levels of vitamin A, irrespective of their dietary intake.<sup>4</sup>

#### How much is usually taken?

For most people, up to 25,000 IU (7,500 mcg) of vitamin A per day is considered safe. However, people over age 65 and those with liver disease should probably not supplement with more than 15,000 IU per day, unless supervised by a doctor. In women who could become **pregnant** (page 363), the maximum safe intake is being re-evaluated. However, less than 10,000 IU (3,000 mcg) per day is generally accepted as safe. There is concern that larger intakes could cause **birth defects** (page 63). Whether the average person would benefit from vitamin A supplementation remains unclear.

#### Are there any side effects or interactions?

Since a 1995 report from the *New England Journal of Medicine*,<sup>5</sup> women who are or could become **pregnant** (page 363) have been told by doctors to take less than 10,000 IU (3,000 mcg) per day of vitamin A to avoid the risk of **birth defects** (page 63). A recent report studied several hundred women exposed to 10,000–300,000 IU (median exposure of 50,000 IU) per day.<sup>6</sup> Three major malformations occurred in this study, but all could have happened in the absence of vitamin A supplementation. Surprisingly, no congenital malformations happened in any of the 120 infants ex-

posed to maternal intakes of vitamin A that exceeded 50,000 IU per day. In fact, the high-exposure group had a 50% decreased risk for malformations compared with infants not exposed to vitamin A. The authors noted that some previous studies found no link between vitamin A and birth defects, and argued the studies that did find such a link suffered from various weaknesses. A closer look at the recent study reveals a 32% higher than expected risk of birth defects in infants exposed to 10,000–40,000 IU of vitamin A per day, but paradoxically a 37% decreased risk for those exposed to even higher levels. This suggests that both “higher” and “lower” risks may have been due to chance.

Excessive dietary intake of vitamin A has been associated with birth defects in humans in fewer than 20 reported cases over the past 30 years.<sup>7,8</sup> Presently, the level at which vitamin A supplementation may cause birth defects is not known, though combined human and animal data suggest that 30,000 IU per day should be considered safe.<sup>9</sup> Women who are or who could become pregnant should consult with a doctor before supplementing with more than 10,000 IU per day.

Vitamin A supplements can both help and hurt children. Many people have heard that vitamin A supplements support **immune function** (page 255) and prevent **infections** (page 265). This is true under some circumstances. However, vitamin A can also *increase* the risk of infections, according to the findings of a double-blind trial.<sup>10</sup> In a study of African children between six months and five years old, a 44% reduction in the risk of severe **diarrhea** (page 163) was seen in those children given four 100,000–200,000 IU applications of vitamin A (the lower amount for those less than a year old) during an eight-month period. On further investigation, the researchers discovered that the reduction in diarrhea occurred only in children who were very malnourished. For children who were not starving, vitamin A supplementation actually *increased* the risk of diarrhea compared with the placebo group. The vitamin A-supplemented children also had a 67% *increased* risk of coughing and rapid breathing, signs of further lung infection, although this problem did not appear in children infected with AIDS. These findings should be of concern to American parents, whose children are not usually infected with AIDS or severely malnourished. Such relatively healthy children fared poorly in the African trial in terms of both the risk of diarrhea and the risk of continued lung problems. Vitamin A pro-

vided no benefit to the well-nourished kids. Therefore, it makes sense to *not* give vitamin A supplements to children unless there is a special reason to do so, such as the presence of a condition causing **malabsorption** (page 304) (e.g., **celiac disease** [page 102]).

In a study of people with retinitis pigmentosa (a degenerative condition of the eye), participants received 15,000 IU of vitamin A per day for 12 years with no signs of adverse effects or toxicity.<sup>11</sup> For other adults, intake above 25,000 IU (7,500 mcg) per day can—in rare cases—cause headaches, dry skin, hair loss, fatigue, bone problems, and liver damage.<sup>12</sup> At higher levels (for example 100,000 IU per day) these problems become more common.

A controlled clinical trial showed that people who took 25,000 IU of vitamin A per day for a median of 3.8 years had an 11% increase in **triglycerides** (page 235), a 3% increase in total **cholesterol** (page 223) and a 1% decrease in HDL cholesterol compared to those who did not take vitamin A.<sup>13</sup> Although the significance of these findings is not clear, people at risk for **cardiovascular disease** (page 98) should use caution when considering long-term vitamin A supplementation.

One study found that increasing the intake of vitamin A in the diet was associated with bone loss and risk of hip fracture, possibly due to a vitamin A-induced stimulation of cells that break down bone.<sup>14</sup> In this study, a vitamin A intake greater than 5,000 IU per day, when compared to a lower intake, was associated with a reduction in bone mineral density that approximately doubles the risk of hip fracture. **Beta-carotene** (page 469) (which can be used by the body to make vitamin A) has not been linked to reduced bone mass. Until more is known, people concerned about **osteoporosis** (page 333) may consider taking beta-carotene supplements rather than supplementing with vitamin A.

Data from test tube, animal, and human studies show that excessive vitamin A intake can accelerate bone loss and inhibit formation of new bone, increasing the risk of osteoporosis.<sup>15</sup> In humans, small studies have found these effects at about 85,000–125,000 IU per day.<sup>16, 17</sup>

Taking vitamin A and **iron** (page 540) together helps overcome **iron deficiency** (page 278) more effectively than iron supplementation alone.<sup>18</sup> Supplementation with **zinc** (page 614), iron, or the combination has been found to improve vitamin A status among children at high risk for deficiency of the three nutrients.<sup>19</sup>

## VITAMIN B<sub>1</sub>

### What is it?

Vitamin B<sub>1</sub> is a water-soluble vitamin needed to process carbohydrates, fat, and protein. Every cell of the body requires vitamin B<sub>1</sub> to form the fuel the body runs on—adenosine triphosphate (ATP). Nerve cells require vitamin B<sub>1</sub> in order to function normally.

### Where is it found?

Wheat germ, whole wheat, peas, beans, enriched flour, fish, peanuts, and meat are all good sources of vitamin B<sub>1</sub>.

**Vitamin B<sub>1</sub> has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Anemia</b> (page 25) (for genetic thiamine-responsive anemia)
★★☆	<b>Alzheimer's disease</b> (page 19) <b>Canker sores</b> (page 90) Childhood intelligence (for deficiency) <b>Diabetes</b> (page 152) Dialysis (for encephalopathy and neurologic damage; take only under medical supervision) <b>Hepatitis</b> (page 220) <b>Low back pain</b> (page 293) (in combination with <b>vitamin B<sub>6</sub></b> [page 600] and <b>vitamin B<sub>12</sub></b> [page 601])
★☆☆	<b>Cardiomyopathy</b> (page 95) (only for wet beri beri) <b>Dysmenorrhea</b> (page 171) (painful menstruation) <b>Fibromyalgia</b> (page 191) <b>HIV support</b> (page 239) <b>Multiple sclerosis</b> (page 323) <b>Pre- and post-surgery health</b> (page 357)

### Who is likely to be deficient?

A decline in vitamin B<sub>1</sub> levels occurs with age, irrespective of medical condition.<sup>1</sup> Deficiency is most commonly found in **alcoholics** (page 12), people with **malabsorption** (page 304) conditions, and those eating a very poor diet. It is also common in children with congenital heart disease.<sup>2</sup> People with **chronic fatigue syndrome** (page 111) may also be deficient in vitamin

B<sub>1</sub>.<sup>3, 4</sup> Individuals undergoing regular kidney dialysis may develop severe vitamin B<sub>1</sub> deficiency, which can result in potentially fatal complications.<sup>5</sup> Persons receiving dialysis should discuss the need for vitamin B<sub>1</sub> supplementation with their physician.

#### How much is usually taken?

While the ideal intake is uncertain, one study reported the healthiest people consumed more than 9 mg per day.<sup>6</sup> The amount found in many **multivitamin** (page 559) supplements (20–25 mg) is more than adequate for most people.

Vitamin B<sub>1</sub> is nontoxic, even in very high amounts.

#### Are there any side effects or interactions?

Vitamin B<sub>1</sub> works hand in hand with **vitamin B<sub>2</sub>** (page 598) and **vitamin B<sub>3</sub>** (page 598). Therefore, nutritionists usually suggest that vitamin B<sub>1</sub> be taken as part of a **B-complex** (page 603) vitamin or other **multivitamin supplement** (page 559).

## VITAMIN B<sub>2</sub>

#### What is it?

Vitamin B<sub>2</sub> is a water-soluble vitamin needed to process **amino acids** (page 465) and fats, activate **vitamin B<sub>6</sub>** (page 600) and **folic acid** (page 520), and help convert carbohydrates into the fuel the body runs on—adenosine triphosphate (ATP). Under some conditions, vitamin B<sub>2</sub> can act as an **antioxidant** (page 467).

#### Where is it found?

Dairy products, eggs, and meat contain significant amounts of vitamin B<sub>2</sub>. Leafy green vegetables, whole grains, and enriched grains contain some vitamin B<sub>2</sub>.

#### Vitamin B<sub>2</sub> has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Anemia</b> (page 25) (if deficient) <b>Migraine headaches</b> (page 316)
★★☆	<b>Canker sores</b> (page 90) <b>Cataracts</b> (page 101) <b>Parkinson's disease</b> (page 345)
★☆☆	<b>Preeclampsia</b> (page 361) <b>Sickle cell anemia</b> (page 403)

#### Who is likely to be deficient?

Vitamin B<sub>2</sub> deficiency can occur in **alcoholics** (page 12). Also, a deficiency may be more likely in people with **cataracts** (page 101)<sup>1, 2</sup> or **sickle cell anemia** (page 403).<sup>3</sup> In developing countries, vitamin B<sub>2</sub> deficiency has been found to be a risk factor for the development of **preeclampsia** (page 361) in **pregnant** (page 363) women.<sup>4</sup> People with **chronic fatigue syndrome** (page 111) may be deficient in vitamin B<sub>2</sub>.<sup>5</sup>

#### How much is usually taken?

The ideal level of intake is not known. The amounts found in many **multivitamin** (page 559) supplements (20–25 mg) are more than adequate for most people.

#### Are there any side effects or interactions?

At supplemental and dietary levels, vitamin B<sub>2</sub> is non-toxic.

Vitamin B<sub>2</sub> works with **vitamin B<sub>1</sub>** (page 597), **vitamin B<sub>3</sub>** (page 598), and **vitamin B<sub>6</sub>** (page 600). For that reason, vitamin B<sub>2</sub> is often taken as part of a **B-complex** (page 603) supplement.

## VITAMIN B<sub>3</sub> (NIACIN, NIACINAMIDE)

#### What is it?

The body uses the water-soluble vitamin B<sub>3</sub> in the process of releasing energy from carbohydrates. It is needed to form fat from carbohydrates and to process alcohol. The niacin form of vitamin B<sub>3</sub> also regulates **cholesterol** (page 223), though niacinamide does not.

Vitamin B<sub>3</sub> comes in two basic forms—niacin (also called nicotinic acid) and niacinamide (also called nicotinamide). A variation on niacin, called inositol hexaniacinate, is also available in supplements. Since it has not been linked with any of the usual niacin toxicity in scientific research, some doctors recommend inositol hexaniacinate for people who need large amounts of niacin.

#### Where is it found?

The best food sources of vitamin B<sub>3</sub> are peanuts, **brewer's yeast** (page 480), fish, and meat. Some vitamin B<sub>3</sub> is also found in whole grains.

**Vitamin B<sub>3</sub> has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Acne</b> (page 4) (topical niacinamide) <b>High cholesterol</b> (page 223) <b>High triglycerides</b> (page 235) (niacin) <b>Intermittent claudication</b> (page 276) (niacin–inositol hexaniacinate) <b>Osteoarthritis</b> (page 328) (niacinamide)
★★☆	<b>Dysmenorrhea</b> (page 171) (painful menstruation) (niacin) <b>High cholesterol</b> (page 223) (inositol hexaniacinate) <b>High triglycerides</b> (page 235) (inositol hexaniacinate) <b>Peripheral vascular disease</b> (page 352) (inositol hexaniacinate) <b>Raynaud's disease</b> (page 382) (niacin–inositol hexaniacinate) <b>Schizophrenia</b> (page 393)
★☆☆	<b>Alcohol withdrawal support</b> (page 12) (niacinamide) <b>Anxiety</b> (page 30) (niacinamide) <b>Cataracts</b> (page 101) (niacinamide) <b>Dermatitis herpetiformis</b> (page 151) (nicotinamide, when combined with tetracycline) <b>Diabetes</b> (page 152) (niacinamide) <b>HIV support</b> (page 239) <b>Hypoglycemia</b> (page 251) (niacinamide) <b>Hypothyroidism</b> (page 252) (niacin) <b>Multiple sclerosis</b> (page 323) (niacin) <b>Photosensitivity</b> (page 356) (niacinamide) <b>Tardive dyskinesia</b> (page 425) (niacin or niacinamide)

### Who is likely to be deficient?

Pellagra, the disease caused by a vitamin B<sub>3</sub> deficiency, is rare in Western societies. Symptoms include loss of appetite, skin rash, **diarrhea** (page 163), mental changes, beefy tongue, and digestive and emotional disturbance.

### How much is usually taken?

In part because it is added to white flour, most people generally get enough vitamin B<sub>3</sub> from their diets to prevent a deficiency. However, 10–25 mg of the vitamin can be taken as part of a **B-complex** (page 603) or **multivitamin** (page 559) supplement. Larger amounts are used for the treatment of various health conditions.

### Are there any side effects or interactions?

Niacinamide is almost always safe to take, though rare liver problems have occurred at amounts in excess of 1,000 mg per day. Niacin, in amounts as low as 50–100 mg, may cause flushing, headache, and **stomachache** (page 260) in some people. Doctors sometimes prescribe very high amounts of niacin (as much as 3,000 mg per day or more) for certain health problems. These large amounts can cause liver damage, **diabetes** (page 152), **gastritis** (page 195), damage to eyes, and elevated blood levels of uric acid (which can cause **gout** [page 208]). Symptoms caused by niacin supplements, such as flushing, have been reduced with sustained-release (also called “time-release”) niacin products. However, sustained-release forms of niacin have caused significant liver toxicity and, rarely, liver failure.<sup>1, 2, 3, 4, 5</sup> One partial time-release (intermediate-release) niacin product has demonstrated clinical efficacy without flushing, and also without the liver function abnormalities typically associated with sustained-release niacin formulations.<sup>6</sup> However, this form of niacin is available by prescription only.

In a controlled clinical trial, 1,000 mg or more per day of niacin raised blood levels of **homocysteine** (page 234), a substance associated with increased risk of **heart disease** (page 98).<sup>7</sup> Since other actions of niacin lower heart disease risk,<sup>8, 9</sup> the importance of this finding is unclear. Nonetheless, for all of the reasons discussed above, large amounts of niacin should never be taken without consulting a doctor.

The inositol hexaniacinate form of niacin has not been linked with the side effects associated with niacin supplementation. In a group of people being treated alternatively with niacin and inositol hexaniacinate for skin problems, niacin supplementation (50–100 mg per day) was associated with numerous side effects, including skin flushing, nausea, vomiting and agitation.<sup>10</sup> In contrast, people taking inositol hexaniacinate experienced no complaints whatsoever, even at amounts two to five times higher than the previously used amounts of niacin. However, the amount of research studying the safety of inositol hexaniacinate remains quite limited. Therefore, people taking this supplement in large amounts (2,000 mg or more per day) should be under the care of a doctor.

Vitamin B<sub>3</sub> works with **vitamin B<sub>1</sub>** (page 597) and **vitamin B<sub>2</sub>** (page 598) to release energy from carbohydrates. Therefore, these vitamins are often taken together in a **B-complex** (page 603) or **multivitamin** (page 559) supplement (although most B<sub>3</sub> research uses niacin or niacinamide alone).

## VITAMIN B<sub>6</sub>

### What is it?

Vitamin B<sub>6</sub> is the master vitamin for processing **amino acids** (page 465)—the building blocks of all proteins and some hormones. Vitamin B<sub>6</sub> helps to make and take apart many amino acids and is also needed to make the hormones, serotonin, **melatonin** (page 555), and dopamine.

Vitamin B<sub>6</sub> aids in the formation of several neurotransmitters and is therefore an essential nutrient in the regulation of mental processes and possibly mood.

In combination with **folic acid** (page 520) and **vitamin B<sub>12</sub>** (page 601), vitamin B<sub>6</sub> lowers **homocysteine** (page 234) levels—an amino acid linked to **heart disease** (page 98) and **stroke** (page 419), and possibly other diseases as well, such as **osteoporosis** (page 333), and **Alzheimer's disease** (page 19).

A rare, but severe, form of childhood **epilepsy** (page 183) results from an inborn error in the metabolism of vitamin B<sub>6</sub>. Children with this form of epilepsy have an abnormal dependence on vitamin B<sub>6</sub> and are usually mentally retarded. Seizure activity is reversible with intravenous injections of vitamin B<sub>6</sub>, which must be administered by a doctor.<sup>1</sup>

In some,<sup>2,3</sup> but not all,<sup>4</sup> studies, vitamin B<sub>6</sub> supplements improved glucose tolerance in women with **diabetes** (page 152) caused by **pregnancy** (page 363).

### Where is it found?

Potatoes, bananas, raisin bran cereal, lentils, liver, turkey, and tuna are all good sources of vitamin B<sub>6</sub>.

**Vitamin B<sub>6</sub> has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Anemia</b> (page 25) (if deficient and for genetic vitamin B <sub>6</sub> -responsive anemia) <b>Autism</b> (page 63) <b>Depression</b> (page 145) (in women taking oral contraceptives) <b>High homocysteine</b> (page 234) (in combination with <b>folic acid</b> [page 520] and <b>vitamin B<sub>12</sub></b> [page 601]) <b>Morning sickness</b> (page 320) <b>Premenstrual syndrome</b> (page 368)

★★★

**Age-related cognitive decline** (page 8)  
**Asthma** (page 32)

**Sickle cell anemia** (page 403)  
**Stroke** (page 419)  
**Tardive dyskinesia** (page 425)

### Who is likely to be deficient?

Vitamin B<sub>6</sub> deficiencies are thought to be very rare. Vitamin B<sub>6</sub> deficiency can cause impaired **immunity** (page 225), skin lesions, and mental confusion. A marginal deficiency sometimes occurs in **alcoholics** (page 12), patients with kidney failure, and women using oral contraceptives. Some doctors believe that most diets do

not provide optimal amounts of this vitamin. People with kidney failure have an increased risk of vitamin B<sub>6</sub> deficiency.<sup>5</sup> Vitamin B<sub>6</sub> has also been reported to be deficient in some people with **chronic fatigue syndrome** (page 111).<sup>6</sup>

#### How much is usually taken?

The most common supplemental intake is 10–25 mg per day. However, high amounts (100–200 mg per day or even more) may be recommended for certain conditions.

#### Are there any side effects or interactions?

Vitamin B<sub>6</sub> is usually safe, at intakes up to 200 mg per day in adults.<sup>7</sup> However, neurological side effects can sometimes occur at that level.<sup>8</sup> Levels higher than 200 mg are more likely to cause such problems. Vitamin B<sub>6</sub> toxicity can damage sensory nerves, leading to numbness in the hands and feet as well as difficulty walking. The National Academy of Sciences performed an analysis of vitamin B<sub>6</sub> studies. They determined the safe upper limit for long-term use is 100 mg per day. However, under supervision of a healthcare professional, up to 200 mg per day of vitamin B<sub>6</sub> can be safely taken by most men and nonpregnant women for limited periods of time. **Pregnant** (page 363) and breast-feeding women should not take more than 100 mg of vitamin B<sub>6</sub> per day without a doctor's supervision.

Since vitamin B<sub>6</sub> increases the bioavailability of **magnesium** (page 551), these nutrients are sometimes taken together.

## VITAMIN B<sub>12</sub>

#### What is it?

Vitamin B<sub>12</sub> is a water-soluble vitamin needed for normal nerve cell activity, DNA replication, and production of the mood-affecting substance **SAME** (page 583) (S-adenosyl-L-methionine). Vitamin B<sub>12</sub> acts with **folic acid** (page 520) and **vitamin B<sub>6</sub>** (page 600) to control homocysteine levels. An excess of **homocysteine** (page 234) is associated with an increased risk of **heart disease** (page 98), **stroke** (page 419), and potentially other diseases such as **osteoporosis** (page 333) and **Alzheimer's disease** (page 19).

Vitamin B<sub>12</sub> deficiency causes fatigue. Years ago, a small, double-blind trial reported that even some people who are *not* deficient in this vitamin had increased energy after vitamin B<sub>12</sub> injections, compared with the effect of placebo injections.<sup>1</sup> In recent years, however, the relationship between B<sub>12</sub> injections and the energy level of people who are not vitamin B<sub>12</sub>-deficient has been rarely studied. In a preliminary trial, 2,500–5,000 mcg of vitamin B<sub>12</sub>, given by injection every two to three days, led to improvement in 50–80% of a group of people with **chronic fatigue syndrome** (page 111) (CFS), with most improvement appearing after several weeks of vitamin B<sub>12</sub> shots.<sup>2</sup> The ability of vitamin B<sub>12</sub> injections to help people with CFS remains unproven, however. People with CFS interested in considering a trial of vitamin B<sub>12</sub> injections should consult a doctor. Oral or sublingual (administered under the tongue) B<sub>12</sub> supplements are unlikely to obtain the same results as injectable B<sub>12</sub>, because the body's ability to absorb large amounts is relatively poor.

#### Where is it found?

Vitamin B<sub>12</sub> is found in all foods of animal origin, including dairy, eggs, meat, poultry, and fish. According to one report, small, inconsistent amounts occur in seaweed (including nori and chlorella) and tempeh.<sup>3</sup> Many researchers and healthcare professionals believe that people cannot rely on vegetarian sources to provide predictably sufficient quantities of vitamin B<sub>12</sub>. However, another study found substantial amounts of vitamin B<sub>12</sub> in nori (at least 55 mcg per 100 grams of dry weight).<sup>4</sup>

#### Vitamin B<sub>12</sub> has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Anemia</b> (page 25) (if deficient) <b>Depression</b> (page 145) (in people with vitamin B <sub>12</sub> deficiency) <b>High homocysteine</b> (page 234) (combination with <b>folic acid</b> [page 520] and <b>vitamin B<sub>6</sub></b> [page 600]) <b>Pernicious anemia</b> (Vitamin B <sub>12</sub> deficiency)

Rating	Health Concerns

### Who is likely to be deficient?

Vegans (vegetarians who also avoid dairy and eggs) frequently become deficient, though the process often takes many years. People with **malabsorption** (page 303) conditions, including those with tapeworm infestation and those with bacterial overgrowth in the intestines, often suffer from vitamin B<sub>12</sub> deficiency. Malabsorption of vitamin B<sub>12</sub> can also result from pancreatic disease, the effects of gastrointestinal surgery, or various prescription drugs.<sup>5</sup>

Pernicious anemia is a special form of vitamin B<sub>12</sub> malabsorption due to impaired ability of certain cells in the stomach to make intrinsic factor—a substance needed for normal absorption of vitamin B<sub>12</sub>. By definition, all people with pernicious anemia are vitamin B<sub>12</sub>-deficient. They require either vitamin B<sub>12</sub> injections or oral supplementation with very high levels (1000 mcg per day) of vitamin B<sub>12</sub>.

Older people with urinary incontinence<sup>6</sup> and hearing loss<sup>7</sup> have been reported to be at increased risk of B<sub>12</sub> deficiency.

**Infection** (page 265) with *Helicobacter pylori*, a common cause of **gastritis** (page 195) and **ulcers** (page 349), has been shown to cause or contribute to adult vitamin B<sub>12</sub> deficiency. *H. pylori* has this effect by damaging cells in the stomach that make intrinsic factor—a substance needed for normal absorption of vitamin B<sub>12</sub>. In one trial, *H. pylori* was detected in 56% of people with anemia due to vitamin B<sub>12</sub> deficiency. Successful eradication of *H. pylori* led to improved blood levels of B<sub>12</sub> in 40% of those infected.<sup>8</sup> Other studies have also suggested a link between *H. pylori* infection and vitamin B<sub>12</sub> deficiency.<sup>9,10</sup> Elimination of *H. pylori* infection does not always improve vitamin B<sub>12</sub> status. People with *H. pylori* infections should have vitamin B<sub>12</sub> status monitored.

In a preliminary report, 47% of people with **tinnitus** (page 430) and related disorders were found to have vitamin B<sub>12</sub> deficiencies that may be helped by supplementation.<sup>11</sup>

**HIV** (page 239)-infected patients often have low blood levels of vitamin B<sub>12</sub>.<sup>12</sup>

A disproportionate amount of people with psychiatric disorders are deficient in B<sub>12</sub>.<sup>13</sup> Significant vitamin B<sub>12</sub> deficiency is associated with a doubled risk of severe **depression** (page 145), according to a study of physically disabled older women.<sup>14</sup>

A preliminary study found that **postmenopausal** (page 311) women who were in the lowest one-fifth of vitamin B<sub>12</sub> consumption had an increased risk of developing **breast cancer** (page 65).<sup>15</sup>

Although blood levels of vitamin B<sub>12</sub> may be higher in **alcoholics** (page 12), actual body stores of vitamin B<sub>12</sub> in the tissues (e.g., the liver) of alcoholics is frequently deficient.<sup>16, 17</sup>

Low blood levels of vitamin B<sub>12</sub> are sometimes seen in **pregnant** (page 363) women; however, this does not always indicate a vitamin B<sub>12</sub> deficiency.<sup>18</sup> The help of a healthcare professional is needed to determine when a true vitamin B<sub>12</sub> deficiency exists in pregnant women with low blood levels of the vitamin.

Hydroxocobalamin (a form of vitamin B<sub>12</sub>) has been recognized for more than 40 years as an effective antidote to cyanide poisoning. It is currently being used in France for that purpose. Because of its safety, hydroxocobalamin is considered by some researchers to be an ideal treatment for cyanide poisoning.<sup>19</sup>

#### How much is usually taken?

Most people do not require vitamin B<sub>12</sub> supplements. However, vegans should supplement with at least 2 to 3 mcg per day.

People with pernicious anemia are often treated with injections of vitamin B<sub>12</sub>. However, oral administration of 1,000 mcg per day can be used reliably as an alternative to vitamin B<sub>12</sub> injections.<sup>20, 21, 22, 23, 24</sup>

Absorption of vitamin B<sub>12</sub> is reduced with increasing age. Some research suggests that elderly people may benefit from 10 to 25 mcg per day of vitamin B<sub>12</sub>.<sup>25, 26, 27</sup>

When vitamin B<sub>12</sub> is used for therapeutic purposes *other than correcting a deficiency*, injections are usually necessary to achieve results.

Sublingual forms of vitamin B<sub>12</sub> are available,<sup>28</sup> but there is no proof (nor is there any reason to expect) that they offer any advantage to oral supplements (i.e. a sub-lingual preparation is eventually swallowed).

#### Are there any side effects or interactions?

Oral vitamin B<sub>12</sub> supplements are not generally associated with any side effects.

Although quite rare, serious **allergic reactions** (page 14) to *injections* of vitamin B<sub>12</sub> (sometimes even life-threatening) have been reported.<sup>29, 30</sup> Whether these reactions are to the vitamin itself, or to preservatives or other substances in the injectable vitamin B<sub>12</sub> solution, remains somewhat unclear. Most, but not all, injectable vitamin B<sub>12</sub> contains preservatives.

If a person is deficient in vitamin B<sub>12</sub> and takes 1,000 mcg or more of **folic acid** (page 520) per day, the folic acid supplementation can improve the anemia caused

by vitamin B<sub>12</sub> deficiency. The effect of folic acid on vitamin B<sub>12</sub> deficiency-induced anemia is not a folic acid toxicity. Rather, the folic acid supplementation is acting to correct one of the problems caused by B<sub>12</sub> deficiency. The other problems caused by a lack of vitamin B<sub>12</sub> (mostly neurological) do *not* improve with folic acid supplements, and can become irreversible if vitamin B<sub>12</sub> is not provided to someone who is vitamin B<sub>12</sub> deficient.

Some doctors are unaware that vitamin B<sub>12</sub> deficiencies often occur *without* anemia—even in people who do not take folic acid supplements. This lack of knowledge can delay diagnosis and treatment of people with vitamin B<sub>12</sub> deficiencies. This can lead to permanent injury. When such a delayed diagnosis occurs in someone who inadvertently erased the anemia of vitamin B<sub>12</sub> deficiency by taking folic acid supplements, the folic acid supplementation is often blamed for the missed diagnosis. This problem is rare and should not occur in people whose doctors understand that a lack of anemia does not rule out a vitamin B<sub>12</sub> deficiency. Anyone supplementing 1,000 mcg or more per day of folic acid should be initially evaluated by a doctor before the folic acid can obscure a proper diagnosis of a possible B<sub>12</sub> deficiency.

## VITAMIN B-COMPLEX

The vitamin B-complex refers to all of the known essential water-soluble vitamins except for **vitamin C** (page 604). These include **thiamine** (page 597) (vitamin B<sub>1</sub>), **riboflavin** (page 598) (vitamin B<sub>2</sub>), **niacin** (page 598) (vitamin B<sub>3</sub>), **pantothenic acid** (page 568) (vitamin B<sub>5</sub>), pyridoxine (**vitamin B<sub>6</sub>** [page 600]), **biotin** (page 473), **folic acid** (page 520), and the cobalamins (**vitamin B<sub>12</sub>** [page 601]).

“Vitamin B” was once thought to be a single nutrient that existed in extracts of rice, liver, or yeast. Researchers later discovered these extracts contained several vitamins, which were given distinguishing numbers. Unfortunately, this has led to an erroneous belief among non-scientists that these vitamins have a special relationship to each other. Further adding to confusion has been the “unofficial” designation of other substances as members of the B-complex, such as **choline** (page 546), **inositol** (page 537), and para-aminobenzoic acid (**PABA** [page 567]), even though they are not essential vitamins.

Each member of the B-complex has a unique structure and performs unique functions in the human body. Vitamins B<sub>1</sub>, B<sub>2</sub>, B<sub>3</sub>, and biotin participate in different aspects of energy production, vitamin B<sub>6</sub> is essential for **amino acid** (page 465) metabolism, and vitamin B<sub>12</sub> and folic acid facilitate steps required for cell division. Each of these vitamins has many additional functions. However, contrary to popular belief, no functions require all B-complex vitamins simultaneously.

Human requirements for members of the B-complex vary considerably—from 3 mcg per day for vitamin B<sub>12</sub> to 18 mg per day for vitamin B<sub>3</sub> in adult males, for example. Therefore, taking equal amounts of each one—as provided in many B-complex supplements—makes little sense. Furthermore, there is little evidence supporting the use of megadoses of B-complex vitamins to combat everyday stress, boost energy, or control food cravings, unless a person has a deficiency of one or more of them. Again, contrary to popular belief, there is no evidence indicating people should take all B vitamins to avoid an imbalance when one or more individual B vitamin is taken for a specific health condition.

Most **multivitamin-mineral** (page 559) products contain the B-complex along with the rest of the essential vitamins and minerals. Since they are more complete than B-complex vitamins alone, multiple vitamin-mineral supplements are recommended to improve overall micronutrient intake and prevent deficiencies.

#### **Are there any side effects or interactions?**

Vitamin B-complex includes several different components, each of which has the potential to interact with drugs. It is recommended that you discuss the use of vitamin B-complex and your current medication(s) with your doctor or pharmacist.

## **VITAMIN C**

#### **What is it?**

Vitamin C is a water-soluble vitamin that has a number of biological functions.

Acting as an **antioxidant** (page 467), one of vitamin C's important functions is to protect LDL **cholesterol**

(page 223) from oxidative damage. (Only when LDL is damaged does cholesterol appear to lead to **heart disease** (page 98), and vitamin C may be one of the most important antioxidant protectors of LDL.)<sup>1</sup> Vitamin C may also protect against heart disease by reducing the stiffness of arteries and the tendency of platelets to clump together.<sup>2</sup>

The antioxidant properties of vitamin C are thought to protect smokers, as well as people exposed to second-hand smoke, from the harmful effects of free radicals. A controlled trial demonstrated the ability of 3 grams of vitamin C, taken by nonsmokers two hours prior to being exposed to cigarette smoke, to reduce the free radical damage and LDL cholesterol oxidation associated with exposure to cigarette smoke.<sup>3</sup> The smoke-induced decline in total antioxidant defense was also diminished. These beneficial effects were not observed in nonsmokers under normal conditions (no free radical exposure).

Vitamin C is needed to make collagen, the “glue” that strengthens many parts of the body, such as muscles and blood vessels. Vitamin C also plays important roles in **wound healing** (page 319) and as a natural antihistamine. This vitamin also aids in the formation of liver bile and helps to fight viruses and to detoxify alcohol and other substances.

Recently, researchers have shown that vitamin C improves nitric oxide activity.<sup>4</sup> Nitric oxide is needed for the dilation of blood vessels, potentially important in lowering **blood pressure** (page 246) and preventing spasms of arteries in the heart that might otherwise lead to **heart attacks** (page 212). Vitamin C has reversed dysfunction of cells lining blood vessels.<sup>5</sup> The normalization of the functioning of these cells may be linked to prevention of heart disease.

Evidence indicates that vitamin C levels in the eye decrease with age<sup>6</sup> and that supplementing with vitamin C prevents this decrease,<sup>7</sup> possibly leading to a lower risk of developing **cataracts** (page 101).<sup>8, 9</sup> Healthy people have been reported in some, but not all, studies<sup>10</sup> to be more likely to take vitamin C and **vitamin E** (page 609) supplements than are people with cataracts.<sup>11</sup>

Vitamin C has been reported to reduce activity of the **enzyme** (page 506), aldose reductase, in people.<sup>12</sup> Aldose reductase is the enzyme responsible for accumulation of sorbitol in eyes, nerves, and kidneys of people with **diabetes** (page 152). This accumulation is believed to be responsible for deterioration of these parts

of the body associated with diabetes. Therefore, interference with the activity of aldose reductase theoretically helps protect people with diabetes.

Vitamin C may help protect the body against accumulation or retention of the toxic mineral, lead. In one preliminary study, people with higher blood levels of vitamin C had much lower risk of having excessive blood levels of lead.<sup>13</sup> In a controlled trial, male smokers with moderate to high levels of lead received supplements of 1,000 mg per day of vitamin C, 200 mg per day of vitamin C, or a placebo.<sup>14</sup> Only those people taking 1,000 mg per day of vitamin C experienced a drop in the blood lead levels, but the reduction in this group was dramatic.

People with recurrent boils (furunculosis) may have defects in white blood cell function that are correctable with vitamin C supplementation. A preliminary study of people with recurrent boils and defective white blood cell function, found that 1 gram of vitamin C taken daily for four to six weeks, resulted in normalization of white blood cell function.<sup>15</sup> Ten of twelve people receiving vitamin C became symptom-free within one month and remained so for periods of one to three years without additional supplementation. The other two people required long-term vitamin C supplementation to prevent recurrences.

A double-blind trial found that 500 mg of vitamin C per day for one year reduced the risk of developing reflex sympathetic dystrophy (a painful nerve condition of the extremities), after a wrist fracture.<sup>16</sup>

In a small, preliminary trial, vitamin C (500 mg twice daily) combined with rutoside (500 mg twice daily), a derivative of the **flavonoid** (page 516), rutin, produced marked improvement in three women with progressive pigmented purpura (PPP), a mild skin condition.<sup>17</sup> Although not a serious medical condition, cosmetic concerns lead people with PPP to seek treatment with a variety of drugs. The vitamin C/rutoside combination represents a promising, non-toxic alternative to these drug treatments, but larger, controlled trials are needed to confirm these preliminary results.

#### Where is it found?

Broccoli, red peppers, currants, Brussels sprouts, parsley, potatoes, citrus fruit, and strawberries are good sources of vitamin C.

**Vitamin C has been used in connection with the following conditions** (refer to the individual health concern for complete information):

### Who is likely to be deficient?

Although scurvy (severe vitamin C deficiency) is uncommon in Western societies, many doctors believe that most people consume less than optimal amounts. Fatigue, easy **bruising** (page 84), and bleeding gums

are early signs of vitamin C deficiency that occur long before frank scurvy develops. Smokers have low levels of vitamin C and require a higher daily intake to maintain normal vitamin C levels. Women with **preeclampsia** (page 361) have been found to have lower blood levels of vitamin C than women without the condition.<sup>18</sup> Women who have lower blood levels of vitamin C have an increased risk of **gallstones** (page 193).<sup>19</sup>

People with kidney failure have an increased risk of vitamin C deficiency.<sup>20</sup> However, people with kidney failure should take vitamin C only under the supervision of a doctor.

### How much is usually taken?

The recommended dietary allowance (RDA) for vitamin C in nonsmoking adults is 75 mg per day for women and 90 mg per day for men. For smokers, the RDAs are 110 mg per day for women and 125 mg per day for men. Most clinical vitamin C studies have investigated the effects of a broad range of higher vitamin C intakes (100–1,000 mg per day or more), often not looking for (or finding) the “optimal” intake within that range. In terms of **heart disease** (page 98) prevention, as little as 100–200 mg of vitamin C appears to be adequate.<sup>21</sup> Although some doctors recommend 500–1,000 mg per day or more, additional research is needed to determine whether these larger amounts are necessary. Some vitamin C experts propose that adequate intake be considered 200 mg per day because of evidence that the cells of the human body do not take up any more vitamin C when larger daily amounts are used.<sup>22</sup>

Some scientists have recommended that healthy people take multi-gram amounts of vitamin C for the prevention of illness. However, little or no research supports this point of view and it remains controversial. Supplementing more results in an excretion level virtually identical to intake, meaning that consuming more vitamin C does not increase the amount that remains in the body.<sup>23</sup> On the basis of extensive analysis of published vitamin C studies, researchers at the Linus Pauling Institute at Oregon State University have called for the RDA to be increased, but only to 120 mg.<sup>24</sup> This same report reveals that “... 90–100 mg vitamin C per day is required for optimum reduction of chronic disease risk in nonsmoking men and women.” Thus, the multiple gram amounts of vitamin C taken by many healthy people may be superfluous.

The studies that ascertained approximately 120–200 mg daily of vitamin C is correct for prevention pur-

poses in healthy people have typically not investigated whether people suffering from various diseases can benefit from larger amounts. In the case of the **common cold** (page 129), a review of published trials found that amounts of 2 grams per day in children appear to be more effective than 1 gram per day in adults, suggesting that large intakes of vitamin C may be more effective than smaller amounts, at least for this condition.<sup>25</sup>

#### Are there any side effects or interactions?

Some people develop **diarrhea** (page 163) after as little as a few grams of vitamin C per day, while others are not bothered by ten times this amount. Strong scientific evidence to define and defend an upper tolerable limit for vitamin C is not available. A review of the available research concluded that high intakes (2–4 grams per day) are well-tolerated by healthy people.<sup>26</sup> However, intake of large amounts of vitamin C can deplete the body of **copper** (page 499)<sup>27, 28</sup>—an essential nutrient. People should be sure to maintain adequate copper intake at higher intakes of vitamin C. Copper is found in many **multivitamin-mineral** (page 559) supplements. Vitamin C increases the absorption of **iron** (page 540) and should be avoided by people with iron overload diseases (e.g., hemochromatosis, hemosiderosis). Vitamin C helps recycle the **antioxidant** (page 467), **vitamin E** (page 609).

It is widely (and mistakenly) believed that mothers who consume large amounts of vitamin C during **pregnancy** (page 363) are at risk of giving birth to an infant with a higher-than-normal requirement for the vitamin. The concern is that the infant could suffer “rebound scurvy,” a vitamin C deficiency caused by not having this increased need met. Even some medical textbooks have subscribed to this theory.<sup>29</sup> In fact, however, the concept of “rebound scurvy” in infants is supported by extremely weak evidence.<sup>30</sup> Since the publication in 1965 of the report upon which this mistaken notion is based, millions of women have consumed high amounts of vitamin C during pregnancy and not a single new case of rebound scurvy has been reported.<sup>31</sup>

A preliminary study found that people who took 500 mg per day of vitamin C supplements for one year had a greater increase in wall thickness of the carotid arteries (vessels in the neck that supply blood to the brain) than those who did not take vitamin C.<sup>32</sup> Thickness of carotid artery walls is an indicator of progression of **atherosclerosis** (page 38). Currently, no evidence supports a cause-and-effect relationship for the outcome

reported in this study. The vast preponderance of research suggests either a protective or therapeutic effect of vitamin C for **heart disease** (page 98), or no effect at all.

**People with the following conditions should consult their doctor before supplementing with vitamin C:** glucose-6-phosphate dehydrogenase deficiency, iron overload (hemochromatosis or hemochromatosis), history of kidney stones, or kidney failure.

It has been suggested that people who form calcium oxalate **kidney stones** (page 284) should avoid vitamin C supplements, because vitamin C can be converted into oxalate and increase urinary oxalate.<sup>33, 34</sup> Initially, these concerns were questioned because of potential errors in the laboratory measurement of oxalate.<sup>35, 36</sup> However, using newer methodology that rules out this problem, recent evidence shows that as little as 1 gram of vitamin C per day can increase the urinary oxalate levels in some people, even those without a history of kidney stones.<sup>37, 38</sup> In one case, 8 grams per day of vitamin C led to dramatic increases in urinary oxalate excretion and kidney stone crystal formation causing bloody urine.<sup>39</sup> People with a history of kidney stones should consult a doctor before taking large amounts (1 gram or more per day) of supplemental vitamin C.

Despite possible therapeutic effects of vitamin C in people with **diabetes** (page 152) at lower intakes, one case of *increased* blood sugar levels was reported after taking 4.5 grams per day.<sup>40</sup>

## VITAMIN D

#### What is it?

The fat-soluble vitamin D's most important role is maintaining blood levels of **calcium** (page 483), which it accomplishes by increasing absorption of calcium from food and reducing urinary calcium loss. Both effects keep calcium in the body and therefore spare the calcium that is stored in bones. When necessary, vitamin D transfers calcium from the bone into the bloodstream, which does not benefit bones. Although the overall effect of vitamin D on the bones is complicated, some vitamin D is necessary for healthy bones and teeth.

Vitamin D plays a role in **immunity** (page 255) and blood cell formation and also helps cells “differentiate”—a process that may reduce the risk of **cancer** (page 87). From animal and human studies, researchers have hypothesized that vitamin D may protect people from **multiple sclerosis** (page 323),<sup>1</sup> autoimmune arthritis, and juvenile **diabetes** (page 152).<sup>2</sup>

Vitamin D is also needed for adequate blood levels of insulin.<sup>3</sup> Vitamin D receptors have been found in the pancreas where insulin is made, and preliminary evidence suggests that supplementation may increase insulin secretion for some people with adult-onset (type 2) **diabetes** (page 152).<sup>4</sup>

### Where is it found?

**Cod liver oil** (page 514) is an excellent dietary source of vitamin D, as are vitamin D-fortified foods. Traces of vitamin D are found in egg yolks and butter. However, the majority of vitamin D in the body is created during a chemical reaction that starts with sunlight exposure to the skin. Cholecalciferol (vitamin D<sub>3</sub>) is the animal form of this vitamin.

**Vitamin D has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Crohn's disease</b> (page 141) <b>Cystic fibrosis</b> (page 143) <b>Osteoporosis</b> (page 333) <b>Rickets/osteomalacia</b> (page 392)

★★★	<b>Alcohol withdrawal support</b> (page 12) <b>Amenorrhea</b> (page 22) (calcium for preventing bone loss) <b>Breast cancer</b> (page 65) (reduces risk) <b>Cardiac arrhythmia</b> (page 93) <b>Colon cancer</b> (page 123) (reduces risk) <b>Diabetes</b> (page 152) <b>Migraine headaches</b> (page 316) <b>Multiple sclerosis</b> (page 323) <b>Parkinson's disease</b> (page 345) <b>Vitiligo</b> (page 443) (topical calcipotriol only)

### Who is likely to be deficient?

In adults, vitamin D deficiency may result in a softening of the bones known as **osteomalacia** (page 392). This condition is treated with vitamin D, sometimes in combination with **calcium** (page 483) supplements. Osteomalacia should be diagnosed, and its treatment monitored, by a doctor. In people of any age, vitamin D deficiency causes abnormal bone formation. It occurs more commonly following winter, owing to restricted sunlight exposure during that season. Living in an area with a lot of atmospheric pollution, which can block the sun's ultraviolet rays, also appears to increase the risk of vitamin D deficiency.<sup>5</sup>

Vitamin D deficiency is more common in strict vegetarians (who avoid vitamin D-fortified dairy foods), dark-skinned people,<sup>6</sup> alcoholics, and people with liver or kidney disease. People with liver and kidney disease can make vitamin D but cannot activate it.

Vitamin D deficiency is more common in people suffering from intestinal **malabsorption** (page 304), which may have occurred following previous intestinal surgeries, or from **celiac disease** (page 102).<sup>7</sup> People with insufficient pancreatic function (e.g., those with **pancreatitis** or **cystic fibrosis** [page 143]) tend to be deficient in vitamin D. Vitamin D deficiency is also common in individuals with hyperthyroidism (Graves' disease), particularly women.<sup>8</sup>

In children, vitamin D deficiency is called **rickets** (page 392) and causes a bowing of bones not seen in adults with vitamin D deficiency. Vitamin D deficiency is common among people with **hyperparathyroidism**, a condition in which the parathyroid gland is overactive. In a study of 124 people with mild hyperparathyroidism, vitamin D levels were below normal in 7% of them and suboptimal in 53% of them.<sup>9</sup> Vitamin D deficiency is also common in men with advanced **prostate cancer** (page 371). In one study, 44% of 16 men with advanced prostate cancer had decreased blood levels of vitamin D.<sup>10</sup>

One in seven adults has been reported to be deficient in vitamin D.<sup>11</sup> In one study, 42% of hospitalized patients under age 65 were reported to be vitamin D deficient.<sup>12</sup> In this same study, 37% of the people were found to be deficient in vitamin D, despite the fact they were eating the currently recommended amount of this nutrient. Vitamin D deficiency is particularly common among the elderly. Age-related decline in vitamin D status may be due to reduced absorption, transport, or liver metabolism of vitamin D.<sup>13</sup>

### How much is usually taken?

People who get plenty of sun exposure do not require supplemental vitamin D, since sunlight increases vitamin D synthesis when it strikes bare skin. Although the recommended dietary allowance for vitamin D is 200 IU per day for adults, there is some evidence that elderly people need 800 to 1,000 IU per day for maximum effects on preserving bone density and preventing fractures.<sup>14, 15, 16, 17</sup> Sun-deprived people should take no less than 600 IU per day and ideally around 1,000 IU per day.<sup>18</sup>

### Are there any side effects or interactions?

People with hyperparathyroidism should not take vitamin D without consulting a physician. People with sarcoidosis should not supplement with vitamin D, unless a doctor has determined that their **calcium** (page 483) levels are not elevated. Too much vitamin D taken for long periods of time may lead to headaches, **weight loss** (page 446), and **kidney stones** (page 284). Rarely, excessive vitamin D may even lead to deafness, blindness, increased thirst, increased urination, **diarrhea** (page 163), irritability, children's failure to gain weight, or death.

Most people take 400 IU per day, a safe amount for adults. Some researchers believe that amounts up to 10,000 IU per day are safe for the average healthy adult, although adverse effects may occur even at lower levels among people with hypersensitivity to vitamin D (e.g. hyperparathyroidism).<sup>19</sup> In fact, of all published cases of vitamin D toxicity for which a vitamin D amount is known, only one occurred at a level of intake under 40,000 IU per day.<sup>20</sup> Nevertheless, people wishing to take more than 1,000 IU per day for long periods of time should consult a physician. People should remember the total daily intake of vitamin D includes vitamin D from fortified milk and other fortified foods, **cod liver oil** (page 514), supplements that contain vitamin D, and sunlight. People who receive adequate sunlight exposure do not need as much vitamin D in their diet as do people who receive minimal sunlight exposure.

Vitamin D increases both **calcium** (page 483) and phosphorus absorption and has also been reported to increase absorption of aluminum. Increased blood levels of calcium (which may be a marker for vitamin D status) have been linked to **heart disease** (page 98).<sup>21</sup> Some,<sup>22</sup> but not all,<sup>23</sup> research suggests that vitamin D may slightly raise blood levels of **cholesterol** (page 333) in humans.

## VITAMIN E

### What is it?

Vitamin E is an **antioxidant** (page 467) that protects cell membranes and other fat-soluble parts of the body, such as low-density lipoprotein (LDL; "bad" cholesterol) **cholesterol** (page 333), from damage.

Only when LDL is damaged does cholesterol appear to lead to **heart disease** (page 98), and vitamin E is an important antioxidant protector of LDL.<sup>1</sup> Several studies,<sup>2, 3</sup> including two double-blind trials,<sup>4, 5</sup> have reported that 400 to 800 IU of natural vitamin E per day reduces the risk of heart attacks. Other recent double-blind trials have found either limited benefit<sup>6</sup> or no benefit at all from supplementation with synthetic vitamin E.<sup>7</sup> One of the negative trials used 400 IU of natural vitamin E<sup>8</sup>—a similar amount and form to previous successful trials. In attempting to make sense of these apparently inconsistent findings, the following is clear: less than 400 IU of synthetic vitamin E, even when taken for years, does not protect against heart disease. Whether 400 to 800 IU of natural vitamin E is, or is not, protective remains unclear.

Vitamin E also plays some role in the body's ability to process glucose. Some, but not all, trials suggest that vitamin E supplementation may eventually prove to be helpful in the prevention and treatment of **diabetes** (page 152).

In the last ten years, the functions of vitamin E in the cell have been further clarified. In addition to its antioxidant functions, vitamin E is now known to act through other mechanisms, including direct effects on inflammation, blood cell regulation, connective tissue growth, and genetic control of cell division.<sup>9</sup>

### Where is it found?

Wheat germ oil, nuts and seeds, whole grains, egg yolks, and leafy green vegetables all contain vitamin E. Certain vegetable oils should contain significant amounts of vitamin E. However, many of the vegetable oils sold in supermarkets have had the vitamin E removed in processing. The high amounts found in supplements, often 100 to 800 IU per day, are not obtainable from eating food.

**Vitamin E has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Anemia</b> (page 25) (if deficient) <b>Burns</b> (page 85) (in combination with <b>vitamin C</b> [page 604] for prevention of sunburn only) <b>Epilepsy</b> (page 183) (for children) <b>Immune function</b> (page 255) (for elderly people) <b>Intermittent claudication</b> (page 276) <b>Rheumatoid arthritis</b> (page 387) <b>Tardive dyskinesia</b> (page 425)

### Who is likely to be deficient?

Severe vitamin E deficiencies are rare. People with a genetic defect in a vitamin E transfer protein called thrombotic thrombocytopenic purpura (TTP) have severe vitamin E deficiency, characterized by low blood and tissue levels of vitamin E and progressive nerve abnormalities.<sup>10, 11</sup>

Low vitamin E status has been associated with an

increased risk of **rheumatoid arthritis** (page 387)<sup>12</sup> and major **depression** (page 145).<sup>13</sup> Women with **preeclampsia** (page 361) have been found to have lower blood levels of vitamin E than women without the condition.<sup>14</sup>

Very old people with type 2 **diabetes** (page 152) have shown a significant age-related decline in blood levels of vitamin E, irrespective of their dietary intake.<sup>15</sup>

### Which form is best?

The names of all types of vitamin E begin with either “d” or “dl,” which refer to differences in chemical structure. The “d” form is natural (also known as RRR-alpha tocopherol) and “dl” is synthetic (more correctly known as all-rac-alpha tocopherol). The natural form is more active and better absorbed. Little is known about how the “unnatural” “l” portion of the synthetic “dl” form affects the body, though no clear toxicity has been discovered.

In theory, when a vitamin E supplement is labeled “400 IU” it should have the same level of activity regardless of its source. This is purportedly achieved by using more synthetic vitamin E to reach the same potency as a lesser amount of natural vitamin E. For example, 100 IU of vitamin E requires about 67 mg of the natural form but closer to 100 mg of the synthetic. However, a recent review of the scientific evidence suggests that natural vitamin E probably has greater activity in the body than indicated on the label.<sup>16</sup> Natural vitamin E may be as much as twice as bioavailable as synthetic vitamin E, not 1.36 times as is generally accepted.<sup>17</sup> Many doctors advise people to use only the natural, the “d” form, of vitamin E.

After the “d” or “dl” designation, often the Greek letter “alpha” appears, which also describes the structure. Synthetic “dl” vitamin E is found only in the alpha form—as in “dl-alpha tocopherol.” Natural vitamin E may be found either as alpha—as in “d-alpha tocopherol”—or in combination with beta, gamma, and delta, labeled “mixed”—as in mixed natural tocopherols.

Little is known about the importance of the beta and delta forms of vitamin E, but a debate has arisen concerning gamma tocopherol. In a test tube study, gamma tocopherol was found to be more effective than alpha tocopherol in protecting against certain specific types of oxidative damage.<sup>18</sup> In addition, some research has shown that supplementation with large amounts of alpha tocopherol (such as 1,200 IU per day) increases

the breakdown, and decreases blood levels, of gamma tocopherol.<sup>19</sup>

Human trials with vitamin E have almost always been done with the alpha (not gamma) form. Historically the synthetic “dl” form was used in most trials, but some trials are now using the natural form. The issue of alpha vs. gamma form requires more research before it can be fully understood.

Almost all vitamin E research shows that, when positive results are obtained, hundreds of units per day are required—an amount easily obtained with supplements but impossible with food. Therefore, switching to food sources, as suggested by some researchers, is impractical. On the other hand, the vitamin E occurring naturally in food contains gamma tocopherol and other tocopherols. Thus, it possibly may turn out to be more effective than the vitamin E taken in supplement form. Additional research is needed in this area.

Vitamin E forms are listed as either plain “tocopherol” or tocopheryl followed by the name of what is attached to it, as in “tocopheryl acetate.” The two forms are not greatly different. However, plain tocopherol may be absorbed a little better, while tocopheryl attached forms have a slightly better shelf life. Both forms are active when taken by mouth. However, the skin utilizes the tocopheryl forms very slowly,<sup>20, 21</sup> so those planning to apply vitamin E to the skin should buy plain tocopherol. In health food stores, the most common forms of vitamin E are d-alpha tocopherol and d-alpha tocopheryl acetate or succinate. Both of these d (natural) alpha forms are frequently recommended by doctors. Although the succinate form is slightly weaker than the acetate form, more milligrams of the succinate form are added to supplements to compensate for this small difference in potency. Therefore, 400 IU of either form should have equivalent potency.

### How much is usually taken?

The recommended dietary allowance for vitamin E is low, just 15 mg or approximately 22 International Units (IU) per day. The most commonly recommended amount of supplemental vitamin E for adults is 400 to 800 IU per day. However, some leading researchers suggest taking only 100 to 200 IU per day, since trials that have explored the long-term effects of different supplemental levels suggest no further benefit beyond that amount. In addition, research reporting positive effects with 400 to 800 IU per day has not investigated the ef-

fects of lower intakes.<sup>22</sup> For **tardive dyskinesia** (page 425), the best results have been achieved from 1,600 IU per day,<sup>23</sup> a large amount that should be supervised by a healthcare practitioner.

### Are there any side effects or interactions?

Vitamin E toxicity is very rare and supplements are widely considered to be safe. The National Academy of Sciences has established the daily tolerable upper intake level for adults to be 1,000 mg of vitamin E, which is equivalent to 1,500 IU of natural vitamin E or 1,100 IU of synthetic vitamin E.<sup>24</sup>

In a double-blind study of healthy elderly people, supplementation with 200 IU of vitamin E per day for 15 months had no effect in the incidence of respiratory infections, but increased the severity of those infections that did occur.<sup>25</sup> For elderly individuals, the risks and benefits of taking this vitamin should be assessed with the help of a doctor or nutritionist.

In contrast to trials suggesting vitamin E improves glucose tolerance in people with **diabetes** (page 152), one trial reported that 600 IU per day of vitamin E led to impairment in glucose tolerance in obese people with diabetes.<sup>26</sup> The reason for the discrepancy between reports is not known.

In a double-blind study of people with established **heart disease** (page 98) or **diabetes** (page 152), participants who took 400 IU of vitamin E per day for an average of 4.5 years developed **heart failure** (page 134) significantly more often than did those taking a placebo.<sup>27</sup> Hospitalizations for heart failure occurred in 5.8% of those in the vitamin E group, compared with 4.2% of those in the placebo group, a 38.1% increase. Considering that some other studies have shown a beneficial effect of vitamin E against heart disease, the results of this study are difficult to interpret. Nevertheless, individuals with heart disease or diabetes should consult their doctor before taking vitamin E.

A review of 19 clinical trials of vitamin E supplementation concluded that long-term use of large amounts of vitamin E (400 IU per day or more) was associated with a small (4%) but statistically significant increase in risk of death.<sup>28</sup> Long-term use of less than 400 IU per day was associated with a small and statistically non-significant reduction in death rates. This research has been criticized because many of the studies on which it was based used a combination of nutritional supplements, not just vitamin E. For example, the adverse ef-

fects reported in some of the studies may have been due to the use of large amounts of zinc or synthetic beta-carotene, and may have had nothing to do with vitamin E. It is also possible that long-term use of large amounts of pure alpha-tocopherol may lead to a deficiency of gamma-tocopherol, with potential negative consequences. For that reason, some doctors recommend that people who need to take large amounts of vitamin E take at least part of it in the form of mixed tocopherols.

Patients on kidney dialysis who are given injections of **iron** (page 540) frequently experience “oxidative stress.” This is because iron is a pro-oxidant, meaning that it interacts with oxygen molecules in ways that may damage tissues. These adverse effects of iron therapy may be counteracted by supplementation with vitamin E.<sup>29</sup>

A diet high in unsaturated fat increases vitamin E requirements. Vitamin E and **selenium** (page 584) work together to protect fat-soluble parts of the body.

## VITAMIN K

### What is it?

Vitamin K is needed for proper bone formation and blood clotting. In both cases, vitamin K does this by helping the body transport **calcium** (page 483). Vitamin K is used by doctors when treating an overdose of the drug warfarin. Also, doctors prescribe vitamin K to prevent excessive bleeding in people taking warfarin but requiring surgery.

There is preliminary evidence that vitamin K<sub>2</sub> (menadione), not vitamin K<sub>1</sub> (phylloquinone; phytomenadione), may improve a group of blood disorders known as myelodysplastic syndromes (MDS).<sup>1</sup> These syndromes carry a significantly increased risk of progression to acute myeloid leukemia. Large-scale trials of vitamin K<sub>2</sub> for MDS are needed to confirm these promising early results.

### Where is it found?

Leafy green vegetables, such as spinach, kale, collards, and broccoli, are the best sources of vitamin K. The greener the plant, the higher the vitamin K content.<sup>2</sup> Other significant dietary sources of vitamin K include soybean oil, olive oil, cottonseed oil, and canola oil.<sup>3</sup>

**Vitamin K has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Celiac disease (page 102) (for deficiency only) Crohn's disease (page 141) Cystic fibrosis (page 143) Osteoporosis (page 333)
★☆☆	Acute myeloid leukemia (vitamin K <sub>2</sub> only) <b>Morning sickness</b> (page 320) Myelodysplastic syndromes (vitamin K <sub>2</sub> only) <b>Phenylketonuria</b> (page 354) (if deficient)

### Who is likely to be deficient?

A vitamin K deficiency, which causes uncontrolled bleeding, is rare, except in people with certain **malabsorption diseases** (page 304). However, there are reports of severe vitamin K deficiency developing in hospitalized patients who had poor food intake and were receiving antibiotics.<sup>4</sup> All newborn infants receive vitamin K to prevent deficiencies that sometimes develop in breast-fed infants.

### How much is usually taken?

The recommended dietary allowance for vitamin K is about 1 mcg per 2.2 pounds of body weight per day or about 65 to 80 mcg per day for most adults.<sup>5</sup> This level of intake may be achieved by consuming adequate amounts of leafy green vegetables. However, studies have shown that many men and women aged 18 to 44 years ingest less than the recommended amount of vitamin K.<sup>6,7</sup>

### Are there any side effects or interactions?

Allergic reactions to vitamin K injections have been reported on rare occasions.<sup>8</sup>

Vitamin K facilitates the effects of **calcium** (page 483) in building bone and proper blood clotting.

## WHEY PROTEIN

### What is it?

Whey protein is a mixture of some of the proteins naturally found in milk. The major proteins found in whey protein include beta-lactoglobulin and alpha-lactalbu-

min. Whey protein has one of the highest protein digestibility-corrected amino acid scores (PDCAAS; a measure of protein bioavailability) and is more rapidly digested than other proteins, such as casein (another milk protein).<sup>1</sup>

Alpha-lactalbumin is a whey protein high in the **amino acid tryptophan** (page 465), which the body uses to make the neurotransmitter serotonin. A double-blind study found that supplementing the diet with alpha-lactalbumin helped improve scores on a memory test in people who were vulnerable to experiencing problems with stress.<sup>2</sup> The researchers speculated that the alpha-lactalbumin raised brain serotonin levels in these subjects, which may have improved their tolerance to stress.

### Where is it found?

During the process of making milk into cheese, whey protein is separated from the milk. This whey protein is then incorporated into ice cream, bread, canned soup, infant formulas, and other food products. Supplements containing whey protein are also available.

**Whey protein has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Athletic performance</b> (page 43)
★☆☆	<b>Cancer</b> (page 87) <b>Hepatitis</b> (page 220) <b>HIV infection</b> (page 239) <b>Immune function</b> (page 255) <b>Osteoporosis</b> (page 333) <b>Stress</b> (page 415) <b>Weight loss and obesity</b> (page 446)

### Who is likely to be deficient?

People who do not include dairy foods in their diets do not consume whey protein. However, the amino acids in whey protein are available from other sources, and a deficiency of these amino acids is unlikely.

People who do not include dairy foods in their diets do not consume whey protein. However, the **amino acids** (page 465) in whey protein are available from other sources, and a deficiency of these amino acids is unlikely. In fact, most Americans consume too much, rather than too little, protein.

### How much is usually taken?

Some benefits of whey protein have been demonstrated with as little as 20 grams per day. For **athletes in training** (page 43) a commonly used amount is 25 grams of whey protein per day, and shouldn't exceed 1.2 grams per 2.2 pounds body weight. Most clinical research has used similar amounts of whey protein.

### Are there any side effects or interactions?

People who are **allergic to dairy products** (page 14) could react to whey protein and should, therefore, avoid it.<sup>3</sup> As with protein in general, long-term, excessive intake may be associated with deteriorating kidney function and possibly **osteoporosis** (page 333). However, neither kidney nor bone problems have been directly associated with consumption of whey protein, and the other dietary sources of protein typically contribute more protein to the diet than does whey protein. The possibility that certain proteins in milk may contribute to the development of diabetes in children is controversial. But since whey proteins include some of the same milk proteins, people who are avoiding milk because of concerns about the risk of diabetes should not consume whey protein either.

**Xylitol has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Ear infections</b> (page 383)
	<b>Tooth decay</b> (page 431)

### Who is likely to be deficient?

Xylitol is not an essential nutrient; therefore, no deficiencies are possible.

### How much is usually taken?

For prevention of dental caries (cavities), 7 to 20 grams per day are given, divided into several doses in candies or chewing gum. For prevention of ear infections, 1.7 to 2.0 grams are given five times per day in gum, lozenges, or syrup.

### Are there any side effects or interactions?

Xylitol is recognized as a safe food additive by the U.S. government.<sup>7</sup> Large amounts (30 to 40 grams) taken all at once can produce diarrhea and intestinal gas.

## ZINC

### XYLITOL

#### What is it?

Xylitol is the alcohol form of xylose, which is used as a sweetener in chewing gums and other dietetic products. Xylitol has less effect on blood sugar or insulin levels compared with sucrose,<sup>1</sup> so it may be a useful sugar substitute for **diabetics** (page 152).<sup>2</sup> In addition, xylitol inhibits the growth of several types of bacteria, including those that cause **tooth decay** (page 431) and **ear infections** (page 383).<sup>3, 4, 5, 6</sup>

#### Where is it found?

Xylitol occurs naturally in straw, corncobs, fruit, vegetables, cereals, mushrooms, and some seaweeds. For use in food manufacturing, xylitol is extracted from birch wood chips. Xylitol may be found in many foods labeled as "sugar-free," including hard candies, cookies, chewing gums, soft drinks, and throat lozenges.

#### What is it?

Zinc is an essential mineral that is a component of more than 300 **enzymes** (page 506) needed to **repair wounds** (page 319), maintain fertility in adults and growth in children, synthesize protein, help cells reproduce, preserve vision, boost **immunity** (page 255), and protect against **free radicals** (page 467), among other functions.

In double-blind trials, zinc lozenges have reduced the duration of **colds** (page 129) in adults,<sup>1, 2, 3</sup> but have been ineffective in children.<sup>4</sup> The ability of zinc to shorten colds may be due to a direct, localized anti-viral action in the throat. For the alleviation of cold symptoms, lozenges providing 13–25 mg of zinc, in the form of zinc gluconate, zinc gluconate-glycine, or zinc acetate, are used, typically every two hours while awake, but only for several days. The best effect is obtained when lozenges are used at the first sign of a cold.

Lozenges containing zinc gluconate, zinc gluconate-glycine, or zinc acetate have been effective, whereas most other forms of zinc and lozenges flavored with citric acid,<sup>5</sup> tartaric acid, sorbitol, or mannitol, have been inef-

fective.<sup>6</sup> Trials using forms other than zinc gluconate, zinc gluconate-glycine, or zinc acetate have failed, as have trials that use insufficient amounts of zinc.<sup>7</sup> Therefore, until more is known, people should only use zinc gluconate, zinc gluconate-glycine, or zinc acetate.

Zinc reduces the body's ability to utilize the essential mineral **copper** (page 499). (For healthy people, this interference is circumvented by supplementing with copper, along with zinc.) The ability to interfere with copper makes zinc an important therapeutic tool for people with **Wilson's disease** (page 453)—a genetic condition that causes copper overload.

Zinc supplementation in children in developing countries is associated with improvements in stunted growth, increased weight gain in underweight children, and substantial reductions in the rates of **diarrhea** (page 163) and pneumonia, the two leading causes of death in these settings.<sup>8, 9, 10</sup> Whether such supplementation would help people in better nourished populations remains unclear.

A small, preliminary trial has found zinc sulfate to be effective for contact dermatitis (a skin rash caused by contact with an **allergen** (page 14) or irritant).<sup>11</sup> Participants with active skin rashes took approximately 23 mg of zinc (in the form of zinc sulfate) three times daily, for one month. 73% of those taking the zinc sulfate had complete resolution of their skin rashes, while the remaining participants had a 50–75% improvement. Further trials are needed to confirm these preliminary findings, however.

### Where is it found?

Good sources of zinc include oysters, meat, eggs, seafood, black-eyed peas, tofu, and wheat germ.

**Zinc has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Acne</b> (page 4) <b>Acrodermatitis enteropathica</b> (page 7) Childhood intelligence (for deficiency) <b>Common cold/sore throat</b> (page 129) (as lozenges) <b>Down's syndrome</b> (page 169) <b>Infertility (male)</b> (page 305) (for deficiency) <b>Night blindness</b> (page 326) (for deficiency) <b>Wilson's disease</b> (page 453) <b>Wound healing</b> (page 319) (oral and topical)

★★★

**Anemia** (page 25) (for thalassemia if deficient)  
**Anorexia nervosa** (page 174)  
**Attention deficit-hyperactivity disorder** (page 55)  
**Birth defects prevention** (page 63)  
**Canker sores** (page 90) (for deficiency only)

**Osgood-Schlatter Disease** (page 327)  
**Osteoarthritis** (page 328) (in combination with **boswellia** [page 644], **ashwagandha** [page 629], and **turmeric** [page 753])  
**Osteoporosis** (page 333)  
**Pre- and post-surgery health** (page 357)  
**Preeclampsia** (page 361)  
**Prostatitis** (page 377) (CBP, NBP)

### Who is likely to be deficient?

Zinc deficiencies are quite common in people living in poor countries. Phytate, a substance found in unleavened bread (pita, matzos, and some crackers) significantly reduces absorption of zinc, increasing the chance of zinc deficiency. However, phytate-induced deficiency of zinc appears to be a significant problem only for people already consuming marginally low amounts of zinc.

Even in developed countries, low-income **pregnant** (page 363) women and pregnant teenagers are at risk for marginal zinc deficiencies. Supplementing with 25–30 mg per day improves pregnancy outcome in these groups.<sup>12, 13</sup>

People with **liver cirrhosis** (page 290) appear to be commonly deficient in zinc.<sup>14</sup> This deficiency may be due to cirrhosis-related zinc **malabsorption** (page 304).<sup>15</sup>

People with Down's syndrome are also commonly deficient in zinc.<sup>16</sup> Giving zinc supplements to children with Down's syndrome has been reported to improve impaired immunity<sup>17</sup> and thyroid function,<sup>18</sup> though optimal intake of zinc for people with Down's syndrome remains unclear.

Children with alopecia areata (patchy areas of hair loss) have been reported to be deficient in zinc.<sup>19, 20</sup>

The average diet frequently provides less than the Recommended Dietary Allowance for zinc, particularly in vegetarians. To what extent (if any) these small deficits in zinc intake create clinical problems remains unclear. Nonetheless, a low-potency supplement (15 mg per day) can fill in dietary gaps. Zinc deficiencies are more common in **alcoholics** (page 12) and people with **sickle cell anemia** (page 403), **malabsorption** (page 304) problems, and chronic kidney disease.<sup>21</sup>

### How much is usually taken?

Moderate intake of zinc, approximately 15 mg daily, is adequate to prevent deficiencies. Higher levels (up to 50 mg taken three times per day) are reserved for people with certain health conditions, under the supervision of a doctor. For the alleviation of **cold** (page 129) symptoms, lozenges providing 13–25 mg of zinc in the form zinc gluconate, zinc gluconate-glycine, or zinc acetate are generally used frequently but only for several days.

### Are there any side effects or interactions?

Zinc intake in excess of 300 mg per day has been reported to impair **immune function** (page 255).<sup>22</sup> Some people report that zinc lozenges lead to stomach ache, nausea, mouth irritation, and a bad taste. One source reports that gastrointestinal upset, metallic taste in the mouth, blood in the urine, and lethargy can occur from

chronic oral zinc supplementation over 150 mg per day,<sup>23</sup> but those claims are unsubstantiated. In topical form, zinc has no known side effects when used as recommended. However, using zinc nasal spray has been reported to cause severe or complete loss of smell function in at least ten people. In some of those cases, the loss of smell was long-lasting or permanent.<sup>24</sup>

Preliminary research had suggested that people with **Alzheimer's disease** (page 19) should avoid zinc supplements.<sup>25</sup> More recently, preliminary evidence in four patients actually showed improved mental function with zinc supplementation.<sup>26</sup> In a convincing review of zinc/Alzheimer's disease research, perhaps the most respected zinc researcher in the world concluded that zinc does not cause or exacerbate Alzheimer's disease symptoms.<sup>27</sup>

Zinc inhibits **copper** (page 499) absorption. Copper deficiency can result in anemia, lower levels of HDL ("good") **cholesterol** (page 223), or **cardiac arrhythmias** (page 93).<sup>28, 29, 30</sup> Copper intake should be increased if zinc supplementation continues for more than a few days (except for people with **Wilson's disease** [page 453]).<sup>31</sup> Some sources recommend a 10 to 1 ratio of zinc to copper. Evidence suggests that no more than 2 mg of copper per day is needed to prevent zinc-induced copper deficiency. Many zinc supplements include copper in the formulation to prevent zinc-induced copper deficiency. Zinc-induced copper deficiency has been reported to cause reversible anemia and suppression of bone marrow.<sup>32</sup>

Marginal zinc deficiency may be a contributing factor in some cases of anemia. In a study of women with normocytic anemia (i.e., their red blood cells were of normal size) and low total iron-binding capacity (a blood test often used to assess the cause of anemia), combined **iron** (page 540) and zinc supplementation significantly improved the anemia, whereas iron or zinc supplemented alone had only slight effects.<sup>33</sup> Supplementation with zinc, or zinc and iron together, has been found to improve **vitamin A** (page 595) status among children at high risk for deficiency of the three nutrients.<sup>34</sup>

Zinc competes for absorption with **copper** (page 499), **iron** (page 540),<sup>35, 36</sup> **calcium** (page 483),<sup>37</sup> and **magnesium** (page 551).<sup>38</sup> A **multimineral** (page 559) supplement will help prevent mineral imbalances that can result from taking high amounts of zinc for extended periods of time.

**N-acetyl cysteine** (page 562) (NAC) may increase urinary excretion of zinc.<sup>39</sup> Long-term users of NAC may consider adding supplements of zinc and copper.

P A R T      T H R E E

# Herbs

## UNDERSTANDING HERBAL TERMINOLOGY

There are many words used to describe herbs and their actions on the body. The following is a guide to understanding these unique terms.

### **Adaptogen**

A substance that invigorates or strengthens the system (also called a tonic).

### **Alterative**

A substance that produces a gradual, beneficial change in the body.

### **Alkaloid**

Heterogeneous group of alkaline, organic, compounds containing nitrogen and usually oxygen; generally colorless and bitter-tasting; especially found in seed plants.

### **Analgesic**

A substance that reduces or relieves pain.

### **Anodyne**

A pain relieving agent, less potent than anesthetic or narcotic.

### **Antihelmintic, anthelmintic**

A substance that expels or destroys intestinal worms (also called a vermifuge).

### **Antihydrotic**

A substance that reduces or suppresses perspiration.

### **Antipyretic**

An agent that reduces or prevents fever (also called a febrifuge).

### **Antispasmodic**

An agent that relieves spasms or cramps.

### **Aperient**

A mild and gentle-acting laxative.

### **Aperitif**

An agent that stimulates the appetite.

### **Aphrodisiac**

A substance that increases sexual desire or potency.

### **Aromatic**

A substance with a strong, volatile, fragrant aroma; often with stimulant properties.

### **Astringent**

An agent that contracts or shrinks tissues; it is used to decrease secretions or control bleeding.

### **Bitter tonic**

A substance with an acrid, astringent or disagreeable taste that stimulates flow of saliva and gastric juices.

### **Bolus**

A suppository poultice used for vaginal or rectal application; made by mixing powdered herb material in melted cocoa butter or similar base and hand-forming suppositories as the matrix cools.

### **Calmative**

An agent with mild sedative or hypnotic properties.

### **Carminative**

A substance that stops the formation of intestinal gas and helps expel gas that has already formed.

### **Catarrh**

Inflammation of a mucous membrane, especially of the respiratory tract.

### **Cathartic**

A powerful agent used to relieve severe constipation (also called a purgative).

### **Chologogue**

An agent that stimulates secretion and release of bile.

**Choleretic**

An agent that stimulates the formation of bile.

**Concentration**

The amount of material in a solution in relationship to the amount of solvent; expressed as the ratio.

For example:

- 1:5 concentration means that 5 parts of an extract contains the equivalent of one part of the raw herb;
- 4:1 concentration means that 1 part of an extract contains the equivalent of 4 parts of the raw herb.

**Counterirritant**

An agent that causes a distracting irritation intended to relieve another irritation.

**Decoction**

Extract of a crude drug made by boiling or simmering (cooking) herbs in water; stronger than a tea or infusion.

**Demulcent**

An oily or mucilaginous substance that soothes irritated tissue, especially mucous membranes.

**Diaphoretic**

An agent, taken internally to promote sweating (also called sudorific).

**Diuretic**

An agent that promotes urine production and flow.

**Emetic**

A substance that induces vomiting.

**Emmenagogue**

An agent, taken internally, to promote menstrual flow.

**Emollient**

An externally applied agent that softens or soothes skin.

**Essential oil**

Any of a class of volatile oils that impart the characteristic odors of plants; used especially in perfumes, food flavorings and aromatherapy; also called volatile oil.

**Expectorant**

An agent that increases bronchial secretions and facilitates their expulsion through coughing, spitting or sneezing.

**Extract**

A concentrate, made by steeping raw plant material(s) in solvent (alcohol and/or water), after which the solvent is allowed to evaporate.

**Febrifuge**

An agent that reduces fever (also called an antipyretic).

**Flatulence**

Gas in the stomach or intestines.

**Fluid extract**

A liquid extract of raw plant material(s), usually of a concentration ratio of 1 part raw herb to 1 part solvent (1:1).

**Fomentation**

Application of a warm and moist cloth, soaked in an infusion or decoction, as treatment.

**Galactogogue**

An agent that increases secretion of milk (synonym for lactagogue).

**Galenical**

Herb and other vegetable drugs as distinguished from mineral or chemical remedies; crude drugs and the tinctures, decoctions, and other preparations made from them, as distinguished from the alkaloids and other active principles.

**Glycoside**

Esters containing a sugar component (glycol) and a nonsugar (aglycone) component attached via oxygen or nitrogen bond; hydrolysis of a glycoside yields one or more sugars.

**Hemostatic**

An agent used to stop internal bleeding.

**Herb**

Plant or part of a plant used for medicinal, taste or aromatic purposes.

**Humectant**

A substance used to obtain a moistening effect.

**Hygroscopic**

A substance that readily attracts and retains water.

**Infusion**

Tea made by steeping herb(s) in hot water.

**Lactagogue**

An agent that increases secretion of milk (synonym for galactogogue).

**Laxative**

A substance that promotes bowel movements.

**Maceration**

A process of softening tissues by soaking in liquid.

**Mucilage**

A gelatinous substance, containing proteins and polysaccharides, that soothes inflammation.

**Mucilaginous**

An agent characterized by a gummy or gelatinous consistency.

**Nervine**

An agent that calms nervousness, tension, or excitement.

**Oleoresin**

A homogenous mixture of resin(s) and volatile oil(s).

**Pharmacognosy**

The study of the biochemistry and pharmacology of plant drugs, herbs, and spices.

**Phlogistic**

Referring to inflammation or fever.

**Poultice**

A soft, moist mass applied to the skin to provide heat and moisture.

**Purgative**

A powerful agent used to relieve severe constipation (also called a cathartic).

**Raw herb**

The form of the plant, or plant parts, unchanged by processing other than separation of parts, drying or grinding.

**Resin**

Any of several solid or semi-solid, flammable, natural organic substances soluble in organic solvents and not water; commonly formed in plant secretions; complex chemical mixtures of acrid resins, resin alcohols, resinol, tannols, esters, and resenes.

**Rubefacient**

An agent, applied to the skin, causing a local irritation and redness; for relief of internal pain.

**Salve**

An herbal preparation mixed in oil and thickened with bees wax applied to the skin.

**Saponin**

Any of several surfactant glycosides that produce a soapy lather; found in plants.

**Sedative**

A substance that reduces nervous tension; usually stronger than a calmative.

**Sialogogue**

An agent that stimulates secretion of saliva.

**Solid extract**

An extract of plant material(s) made by removing the solvent from a fluid extract.

**Soporific**

A substance that induces sleep.

**Stimulant**

An agent that excites or quickens a process or activity of the body.

**Stomachic**

An agent that gives strength and tone to the stomach or stimulates the appetite by promoting digestive secretions.

**Styptic**

A substance that stops external bleeding (usually an astringent).

**Sudorific**

An agent, taken internally, to promote sweating (also called diaphoretic).

**Tannin**

A complex mixture of polyphenols; gives a color reaction to iron-containing substances.

**Terpene**

Any of several isomeric hydrocarbons; most volatile oils consist primarily of terpenes.

**Tincture**

A solution prepared by steeping or soaking (maceration) plant materials in alcohol and water.

**Tonic**

A substance that invigorates or strengthens the system (also called adaptogen); tonics often act as stimulants or aperients.

**Vermifuge**

A substance that expels or destroys intestinal worms (also called antihelmintic or anthelmintic).

**Volatile oil**

An odorous plant oil that evaporates readily; also called essential oil.

**Vulnerary**

A substance used in the treatment or healing of wounds.

Herbs are listed by common names; if you don't find what you're looking for, look in the index.

## AHCC

**Common name:** Active Hexose Correlated Compound  
**Botanical name:** Basidiomycetes

### Parts used and where grown

AHCC™ is a newly developed “functional food” made through the hybridization of several kinds of mushrooms belonging to the Basidiomycetes family, including shiitake (*Lentinula edodes*), cultured in a liquid medium. The mushroom’s sources and details of methods of preparation have not been fully disclosed.

**AHCC has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Cancer

### Historical or traditional use (may or may not be supported by scientific studies)

AHCC was not used in traditional medicine. The mushrooms of the type from which AHCC is made were historically used as tonics and for chronic infections, anemia, and a variety of other conditions.<sup>1</sup>

### Active constituents

AHCC consists of polysaccharides, particularly low molecular weight alpha-1,3-glucans, amino acids, and minerals.

### How much is usually taken?

Studies have typically administered 3 grams per day orally.

### Are there any side effects or interactions?

In the studies in which AHCC was given to people with cancer, no side effects or drug interactions were observed. However, thorough studies establishing its safety have not been conducted. There are no reports that AHCC is contraindicated in any condition. Use in pregnancy and lactation have not been studied.

AHCC

## ALDER BUCKTHORN

**Common name:** Frangula  
**Botanical name:** *Rhamnus frangula*

### Parts used and where grown

Alder buckthorn is a tall shrub native to northern Europe. The bark of alder buckthorn is removed, cut into small pieces, and dried for one year before being used medicinally. Fresh bark has an emetic or vomit-inducing property and is therefore not used.

**Alder Buckthorn has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Constipation (page 137)

### Historical or traditional use (may or may not be supported by scientific studies)

Alder buckthorn has been used as a cathartic laxative in northern and central Europe, including England, for centuries.<sup>1</sup> Despite its decline in importance when the similar shrub *Rhamnus purshiana* or *Cascara sagrada* (page 652) was discovered in America,<sup>2</sup> alder buckthorn is still used, particularly in Europe.

### Active constituents

Alder buckthorn is high in anthraquinone glycosides. Resins, tannins, and lipids make up the bulk of the bark’s other ingredients. Anthraquinone glycosides have a cathartic action, inducing the large intestine to increase its muscular contraction (peristalsis) and increasing water movement from the cells of the colon into the feces, resulting in strong, soft bowel movements.<sup>3</sup> It takes six to ten hours for alder buckthorn to act after taking it by mouth.

### How much is usually taken?

Only the dried form of alder buckthorn should be used. Capsules providing 20 to 30 mg of anthraquinone glycosides (calculated as glucofrangulin A) per day can be used; however, the smallest amount necessary to maintain regular bowel movements should be used.<sup>4</sup> As a tincture, 5 ml once at bedtime is generally taken. Alder buckthorn is usually taken at bedtime to induce a bowel movement by morning. It is important to drink

eight six-ounce glasses of water throughout the day while taking alder buckthorn, and to consume plenty of fresh fruits and vegetables. Alder buckthorn should be taken for a maximum of eight to ten days consecutively or else it can lead to dependence on it to have a bowel movement.<sup>5</sup> Some people take **peppermint tea** (page 726) or capsules with alder buckthorn to prevent griping, an unpleasant sensation of strong contractions in the colon sometimes induced by the herb.

#### **Are there any side effects or interactions?**

Alder buckthorn may turn the urine dark yellow or red, but this is harmless. Women who are pregnant or breast-feeding and children under the age of 12 should not use alder buckthorn without the advice of a physician. Those with an intestinal obstruction, **Crohn's disease** (page 141) or any other acute inflammatory problem in the intestines, **diarrhea** (page 163), appendicitis, or abdominal pain should not use this herb.<sup>6</sup> Use or abuse of alder buckthorn for more than ten days consecutively may cause a loss of electrolytes (especially the mineral potassium) or may weaken the colon. Long-term use can also cause kidney damage.<sup>7</sup>

## **ALFALFA**

**Common name:** Lucerne

**Botanical name:** *Medicago sativa*

#### **Parts used and where grown**

Alfalfa, also known as lucerne, is a member of the pea family and is native to western Asia and the eastern Mediterranean region. Alfalfa sprouts have become a popular food. Alfalfa herbal supplements primarily use the dried leaves of the plant. The heat-treated seeds of the plant have also been used.

**Alfalfa has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Menopause</b> (page 311) (in combination with <b>sage</b> [page 740])
★☆☆	<b>High cholesterol</b> (page 223) <b>Menopause</b> (page 311) Poor appetite

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Many years ago, traditional Chinese physicians used young alfalfa leaves to treat disorders of the digestive tract.<sup>1</sup> Similarly, the Ayurvedic physicians of India prescribed the leaves and flowering tops for poor digestion. Alfalfa was also considered therapeutic for water retention and arthritis. North American Indians recommended alfalfa to treat jaundice and to encourage blood clotting.

Although conspicuously absent from many classic textbooks on herbal medicine, alfalfa did find a home in the texts of the Eclectic physicians (19th-century physicians in the United States who used herbal therapies) as a tonic for **indigestion** (page 260), dyspepsia, anemia, loss of appetite, and poor assimilation of nutrients.<sup>2</sup> These physicians also recommended the alfalfa plant to stimulate lactation in nursing mothers, and the seeds were made into a poultice for the treatment of boils and insect bites.

#### **Active constituents**

While the medicinal benefits of alfalfa are poorly understood, the constituents in alfalfa have been extensively studied. The leaves contain approximately 2–3% saponins.<sup>3</sup> Animal studies suggest that these constituents block absorption of **cholesterol** (page 223) and prevent the formation of atherosclerotic plaques.<sup>4</sup> One small human trial found that 120 grams per day of heat-treated alfalfa seeds for eight weeks led to a modest reduction in cholesterol.<sup>5</sup> However, consuming the large amounts of alfalfa seeds (80–120 grams per day) needed to supply high amounts of these saponins may potentially cause damage to red blood cells in the body.<sup>6</sup> Herbalists also claim that alfalfa may be helpful for people with **diabetes** (page 152). But while high amounts of a water extract of the leaves led to increased insulin release in animal studies, there is no evidence that alfalfa would be useful for the treatment of diabetes in humans.<sup>7</sup>

Alfalfa leaves also contain flavones, isoflavones, sterols, and coumarin derivatives. The isoflavones are thought to be responsible for the estrogen-like effects seen in animal studies.<sup>8</sup> Although this has not been confirmed with human trials, alfalfa is sometimes used to treat **menopause** (page 311) symptoms.

Alfalfa contains protein and **vitamin A** (page 595), **vitamin B<sub>1</sub>** (page 597), **vitamin B<sub>6</sub>** (page 600), **vitamin C** (page 604), **vitamin E** (page 609), and **vitamin K** (page 612). Nutrient analysis demonstrates the presence of **calcium** (page 483), **potassium** (page 572), **iron** (page 540), and **zinc** (page 614).

### How much is usually taken?

Dried alfalfa leaf is available as a bulk herb, and in tablets or capsules. It is also available in liquid extracts. No therapeutic amount of alfalfa has been established for humans. Some herbalists recommend 500–1,000 mg of the dried leaf per day or 1–2 ml of tincture three times per day.<sup>9</sup>

**Crohn's disease** (page 141)  
**Gastroesophageal reflux disease** (page 198)  
(GERD)

### Are there any side effects or interactions?

Use of the dried leaves of alfalfa in the amounts listed above is usually safe. There have been isolated reports of people who are allergic to alfalfa. Ingestion of very large amounts (the equivalent of several servings) of the seed and/or sprouts has been linked to the onset of **systemic lupus erythematosus** (page 421) (SLE) in animal studies.<sup>10</sup> It has also been linked to the reactivation of SLE in people consuming alfalfa tablets.<sup>11</sup> SLE is an autoimmune illness characterized by inflamed joints and a high risk of damage to kidneys and other organs. The chemical responsible for this effect is believed to be canavanine.

## ALOE

**Botanical names:** *Aloe vera*, *Aloe barbadensis*

### Parts used and where grown

The aloe plant originally came from Africa. The leaves, which are long, green, fleshy, and have spikes along the edges, are used medicinally. The fresh leaf gel and latex are used for many purposes. Aloe latex is the sticky residue left over after the liquid from cut aloe leaves has evaporated.

**Aloe has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Constipation</b> (page 137)
★★☆	<b>Burns (minor)</b> (page 85) <b>Canker sores</b> (page 90) <b>Diabetes</b> (page 152) <b>Genital herpes</b> (page 200) (topical) <b>Psoriasis</b> (page 379) <b>Seborrheic dermatitis</b> (page 400) (topical) <b>Skin ulcers</b> (page 409) <b>Ulcerative colitis</b> (page 433) <b>Wound healing</b> (page 319) (topical)

### Historical or traditional use (may or may not be supported by scientific studies)

Aloe has been historically used for many of the same conditions for which it is used today—particularly **constipation** (page 137) and minor **cuts** (page 319) and **burns** (page 85). In India, it has been used by herbalists to treat intestinal **infections** (page 265), suppressed menses, and **colic** (page 121).

### Active constituents

The constituents of aloe latex responsible for its laxative effects are known as anthraquinone glycosides. These molecules are split by the normal bacteria in the large intestines to form other molecules (aglycones), which exert the laxative action. Since aloe is such a powerful laxative, other plant laxatives such as senna or **cascara** (page 652) are often recommended first.

Topically, it is not yet clear which constituents are responsible for the **wound healing** (page 319) properties of aloe.<sup>1</sup> Test tube studies suggest polysaccharides, such as acemannan, help promote skin healing by anti-inflammatory, antimicrobial, and immune-stimulating actions. Aloe's effects on the skin may also be enhanced by its high concentration of **amino acids** (page 465), as well as **vitamin E** (page 609), **vitamin C** (page 604), **zinc** (page 614), and essential fatty acids.

Aloe has been used to treat minor **burns** (page 85).<sup>2</sup> Stabilized aloe gel is applied to the affected area of skin three to five times per day. Older case studies reported that aloe gel applied topically could help heal radiation burns,<sup>3</sup> and a small clinical trial found it more effective than a topical petroleum jelly in treating burns.<sup>4</sup> However, a large, modern, placebo-controlled trial did not find aloe effective for treating minor burns.<sup>5</sup>

Two small controlled human trials have found that aloe, either alone or in combination with the oral hypoglycemic drug, glibenclamide, effectively lowers blood sugar in people with type 2 (non-insulin-dependent) **diabetes** (page 152).<sup>6,7</sup>

An aloe extract in a cream has been shown effective in a double-blind, controlled trial in people with **psoriasis** (page 379).<sup>8</sup>

### How much is usually taken?

For **constipation** (page 137), a single 50–200 mg capsule of aloe latex can be taken each day for a maximum of ten days.

For minor **burns** (page 85), the stabilized aloe gel is applied topically to the affected area of skin three to five times per day. Treatment of more serious burns should only be done under the supervision of a healthcare professional. For internal use of aloe gel, two tablespoons (30 ml) three times per day is used by some people for **inflammatory bowel** (page 269) conditions, such as **Crohn's disease** (page 141) and **ulcerative colitis** (page 433) (see precautions below). For type 2 **diabetes** (page 152), clinical trials have used one tablespoon (15 ml) of aloe juice, twice daily. Treatment of diabetes with aloe should only be done under the supervision of a qualified healthcare professional.

### Are there any side effects or interactions?

Except in the rare person who is allergic to aloe, topical application of the gel is generally safe. For any **burn** (page 85) that blisters significantly or is otherwise severe, medical attention is absolutely essential. In some severe burns and **wounds** (page 319), aloe gel may actually impede healing.<sup>9</sup>

The latex form of aloe should not be used by anyone with inflammatory intestinal diseases, such as **Crohn's disease** (page 141), **ulcerative colitis** (page 433), or appendicitis. It should also not be used by children, or by women during **pregnancy** (page 363) or **breast-feeding** (page 74).<sup>10</sup>

In people with constipation, aloe latex should not be used for more than ten consecutive days as it may lead to dependency and fluid loss. Extensive fluid loss may lead to depletion of important electrolytes in the body such as **potassium** (page 572).<sup>11</sup>

## AMERICAN GINSENG

**Botanical name:** *Panax quinquefolius*

### Parts used and where grown

Like its more familiar cousin **Asian ginseng** (page 630) (*Panax ginseng*), the root of American ginseng is used medicinally. The plant grows wild in shady forests of the northern and central United States, as well as in parts of Canada. It is cultivated in the United States, China, and France.

**American ginseng has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Diabetes</b> (page 152)
★☆☆	<b>Athletic performance</b> (page 43) <b>Infection</b> (page 265) Stress

### Historical or traditional use (may or may not be supported by scientific studies)

Many Native American tribes used American ginseng. Medicinal applications ranged from digestive disorders to sexual problems.<sup>1</sup> The Chinese began to use American ginseng after it was imported during the 1700s.<sup>2</sup> The traditional applications of American ginseng in China are significantly different from those for *Panax ginseng* (Asian ginseng).<sup>3</sup>

### Active constituents

American ginseng contains ginsenosides, which are thought to fight fatigue and stress by supporting the adrenal glands and the use of oxygen by exercising muscles.<sup>4</sup> The type and ratio of ginsenosides are somewhat different in American and Asian ginseng. The extent to which this affects their medicinal properties is unclear. A recent preliminary trial with healthy volunteers found no benefit in exercise performance after one week of taking American ginseng.<sup>5</sup>

In a small pilot study, 3 grams of American ginseng was found to lower the rise in blood sugar following the consumption of a drink high in glucose by people with type 2 **diabetes** (page 152).<sup>6</sup> The study found no difference in blood sugar lowering effect if the herb was taken either 40 minutes before the drink or at the same time. A follow-up to this study found that increasing the amount of American ginseng to either 6 or 9 grams did not increase the effect on blood sugar following the high-glucose drink in people with type 2 diabetes.<sup>7</sup> This study also found that American ginseng was equally effective in controlling the rise in blood sugar if it was given up to two hours before or together with the drink.

### How much is usually taken?

Standardized extracts of American ginseng, unlike Asian ginseng, are not available. However, dried root powder, 1–3 grams per day in capsule or tablet form, can be used.<sup>8</sup> Some herbalists also recommend 3–5 ml of tincture three times per day.

### Are there any side effects or interactions?

Occasional cases of **insomnia** (page 270) or agitation have been reported with the use of American ginseng. These conditions are more likely, however, when caffeine-containing foods and beverages are also being consumed.<sup>9</sup>

## AMERICAN SCULLCAP

**Common name:** Scullcap

**Botanical name:** *Scutellaria lateriflora*

### Parts used and where grown

Scullcap is a member of the mint family. *Scutellaria lateriflora* grows in eastern North America and is most commonly used in United States and European herbal products containing scullcap. The above-ground (aerial) part of the plant is used in herbal preparations. It is not interchangeable with **Chinese scullcap** (page 658).

**Scullcap has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Anxiety (page 30) Insomnia (page 270) Pain (page 338)

### Historical or traditional use (may or may not be supported by scientific studies)

As is the case in modern herbal medicine, scullcap was used historically as a sedative for people with nervous tension and **insomnia** (page 270). It was, and continues to be, commonly combined with **valerian** (page 756) for insomnia.<sup>1</sup> It was also used by herbalists as a remedy for **epilepsy** (page 183) and nerve **pain** (page 338).

### Active constituents

Few studies have been completed on the constituents of American scullcap. One of its constituents, scutellarian, has been reportedly shown to have mild sedative and antispasmodic actions in animal studies.<sup>2</sup> Human trials have not yet been conducted to confirm the use of scullcap for **anxiety** (page 30) or insomnia.

### How much is usually taken?

Scullcap tea can be made by pouring 1 cup (250 ml) of boiling water over 1–2 teaspoons (5–10 grams) of the dried herb and steeping for 10 to 15 minutes. This tea may be drunk three times per day.<sup>3</sup> Alternatively, tincture made from fresh scullcap,  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (2–4 ml) three times per day, may be taken.

### Are there any side effects or interactions?

Use of scullcap in the amounts listed above is generally safe. However, scullcap use during **pregnancy** (page 363) and breast-feeding should be avoided due to limited information about its safety. Cases of liver damage have been reported in association with the intake of scullcap. However, on closer examination, it appears these scullcap products actually contained germander (*Teucrium chamaedrys*), an herb known to cause liver damage.<sup>4</sup>

One case report exists of a 28-year-old man who died of liver failure after taking unspecified amounts of scullcap, pau d'arco, and zinc.<sup>5</sup> It appears likely that this, too, may have been a case of adulteration of scullcap with germander.<sup>6</sup>

## ANDROGRAPHIS

**Common names:** Chiretta, chuan xin lian, kalmegh, kirata

**Botanical name:** *Andrographis paniculata*

### Parts used and where grown

*Andrographis* originated in the plains of India, and it also grows in China. The leaves and flowers are used medicinally.

**Andrographis has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Common cold (page 129) Immune function (page 255) Infection (page 265)
★★☆	Dysentery
★☆☆	HIV infection (page 239) Indigestion (page 260) Viral hepatitis (page 220)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Andrographis has long been used in traditional Indian and Chinese herbal medicine. The most common reported uses were for digestive problems (as is the case with most non-toxic bitter herbs such as andrographis), snakebite, and **infections** (page 265) ranging from malaria to dysentery.<sup>1, 2</sup> Interestingly, some of these uses have been validated by modern scientific research. Although the roots were sometimes used in traditional medicine, the leaves and flowers are now more commonly used.

### **Active constituents**

The major constituents in andrographis are diterpene lactones known as andrographolides. These bitter constituents are believed to have **immune-stimulating** (page 255), anti-inflammatory, fertility-decreasing, liver-protective, and bile secretion-stimulating actions.<sup>3</sup> Though some older studies suggested andrographis was antibacterial, modern research has been unable to confirm this finding.<sup>4</sup>

Several double-blind clinical trials have found that andrographis can help reduce symptom severity in people with **common colds** (page 129).<sup>5, 6, 7, 8, 9</sup> Though the earliest clinical trial among these showed modest benefits, later studies have tended to be more supportive. Standardized andrographis extract combined with **eleuthero** (page 672) (Siberian ginseng), known as Kan jang, has also been shown in a double-blind clinical trial to reduce symptoms of the common cold.<sup>10</sup>

A preliminary uncontrolled study using isolated andrographolide found that while it tended to decrease viral load and increase CD4 lymphocyte levels in people with **HIV infection** (page 239), at the amount used, the preparation led to side effects, including headache, fatigue, a bitter/metallic taste in the mouth, and elevated liver enzymes (which returned to normal after the medication was stopped).<sup>11</sup> It is unknown whether the andrographolides used in this study directly killed HIV or had an immune-strengthening effect.

Andrographis has proven helpful in combination with antibiotics for people with dysentery, a severe form of **diarrhea** (page 163).<sup>12</sup> It has also shown preliminary benefit for people with chronic viral **hepatitis** (page 220).<sup>13</sup>

### **How much is usually taken?**

Andrographis is generally available as capsules with dried herb or as standardized extracts (containing 11.2 mg andrographolides per 200 mg of extract). For dried herb,

500–3,000 mg are taken three times per day. In clinical trials, 100 mg of a standardized extract were taken two times per day to treat the **common cold** (page 129).<sup>14</sup> For **indigestion** (page 260), andrographis may be taken as a tea. Use 1 teaspoon (5 grams) of the herb for each cup (250 ml) of hot water. Allow the mixture to stand for 10–15 minutes before drinking (sip before meals).

### **Are there any side effects or interactions?**

Some people develop intestinal upset when taking andrographis. If this occurs, reduce the amount taken or take it with meals. Headache, fatigue, a bitter/metallic taste, and elevated liver enzymes were reported in one trial with HIV-infected people taking high doses of isolated andrographolides.<sup>15</sup> This has not been reported in people using whole andrographis or standardized extracts at the amounts recommended above. As with all bitter herbs, andrographis may aggravate **ulcers** (page 349) and **heartburn** (page 260). The safety of andrographis during **pregnancy** (page 363) and breast-feeding is unknown.

## **ANISE**

**Botanical name:** *Pimpinella anisum*

### **Parts used and where grown**

The seeds of this aromatic plant are used as both medicine and as a cooking spice. Anise comes from Eurasia but is now grown in gardens all over the world.

**Anise has been used in connection with the following conditions** (refer to the individual health concern for complete information):

<b>Rating</b>	<b>Health Concerns</b>
★☆☆	Adjunct to cathartic laxatives <b>Breast-feeding support</b> (page 74) <b>Bronchitis</b> (page 80) <b>Chronic Obstructive Pulmonary Disease</b> (page 114) (COPD) <b>Cough</b> (page 139) <b>Indigestion and gas</b> (page 260) <b>Parasites</b> (page 343)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Anise has been an important flavoring in European cooking since time immemorial. Its oil has also been

used as an anthelmintic—a drug used to remove intestinal **parasites** (page 343)—though it is not considered the strongest plant in this regard.<sup>1</sup> Anise has also been used for centuries in European herbalism to treat **coughs** (page 139) and **indigestion** (page 260).<sup>2</sup>

### Active constituents

The active constituents in anise, particularly the terpenoid anethole, are contained in its volatile oil. The volatile oil gives the plant a delightful flavor and has been combined with other less pleasant tasting medicinal herbs to offset their taste. The oil is also antispasmodic, helping to relieve **intestinal gas** (page 260) and spasmodic **coughs** (page 139).<sup>3</sup> Anise has been combined with cathartic laxatives to help reduce the spasmodic cramping they can cause.<sup>4</sup> It may also have modest antiparasitic actions and has been recommended by some practitioners to treat mild intestinal **parasite** (page 343) infections.<sup>5</sup> Anethole has been documented to have phytoestrogen activity in test tubes and animals;<sup>6</sup> the relevance of this to humans is unknown. No clinical trials have been conducted to support any of these uses, though anise is approved for use by the German Commission E for relieving coughs and indigestion.<sup>7</sup>

### How much is usually taken?

Three grams ( $\frac{1}{2}$  tsp) of the seeds can be used three times per day to treat indigestion. To make a tea, boil 2 to 3 grams ( $\frac{1}{2}$  tsp) of crushed seeds in 250 ml (1 cup) of water for ten to fifteen minutes, keeping the pot covered. Three cups of this tea can be drunk per day. It has been recommended to combine approximately 0.5 ml anise volatile oil with 4 oz (120 ml) tincture of anise and then take 10 to 30 drops ( $\frac{1}{2}$  to 1.5 ml) of this mixture three times daily for coughs.<sup>8</sup> The volatile oil can also be inhaled (by placing it in a vaporizer or in a steaming bowl of water) to help relieve a cough.<sup>9</sup>

### Are there any side effects or interactions?

There are no known adverse effects from anise other than occasional allergic reactions of the skin with topical use and of the respiratory or gastrointestinal tract with internal use. It is frequently used to alleviate cough in children because of its gentleness and pleasant taste.<sup>10</sup> The safety of using anise during **pregnancy** (page 363) and **breast-feeding** (page 74) is unknown, though it is very likely safe and has traditionally been used to support breast-feeding in some cultures.<sup>11</sup>

## ARTICHOKE

**Botanical name:** *Cynara scolymus*

### Parts used and where grown

This large thistle-like plant is native to the regions of southern Europe, North Africa, and the Canary Islands. The leaves of the plant are used medicinally. However, the roots and the immature flower heads may also contain beneficial compounds.<sup>1</sup>

**Artichoke has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Indigestion</b> (page 260) and lack of appetite (digestive aid)
★★☆	<b>High cholesterol</b> (page 223)
★☆☆	<b>Irritable bowel syndrome</b> (page 280)

### Historical or traditional use (may or may not be supported by scientific studies)

The artichoke is one of the world's oldest medicinal plants. The ancient Egyptians placed great value on the plant—it is clearly seen in drawings involving fertility and sacrifice. Moreover, this plant was used by the ancient Greeks and Romans as a digestive aid. In 16th century Europe, the artichoke was favored as a food by royalty.<sup>2</sup>

### Active constituents

Artichoke leaves contain a wide number of active constituents, including cynarin, 1,3 dicaffeoylquinic acid, 3-caffeoylequinic acid, and scolymoside.<sup>3</sup> The choleric (bile stimulating) action of the plant has been well documented in a controlled trial involving a small sample of healthy volunteers.<sup>4</sup> After the administration of 1.92 grams of standardized artichoke extract directly into the duodenum, liver bile flow increased significantly. This choleric effect has led to the popular use of artichoke extract in Europe for the treatment of mild indigestion—particularly following a meal high in fat. In an uncontrolled clinical trial with 553 people suffering from non-specific digestive disorders (including indigestion), 320–640 mg of a standardized artichoke extract taken three times per day was found

to reduce nausea, abdominal pain, **constipation** (page 137), and flatulence in over 70% of the study participants.<sup>5</sup>

The standardized extract has also been used to treat **high cholesterol** (page 223) and **triglycerides** (page 235). In one preliminary trial<sup>6</sup> and one controlled trial,<sup>7</sup> use of a standardized artichoke extract was found to lower cholesterol and triglycerides significantly when taken in amounts ranging from 900 to 1,920 mg per day. One preliminary trial failed to find any effect.<sup>8</sup>

While scientists are not certain how artichoke leaves lower cholesterol, test tube studies have suggested that the action may be due to an inhibition of cholesterol synthesis and/or the increased elimination of cholesterol because of the plant's choleric action.<sup>9</sup> In test tube studies, the **flavonoids** (page 516) from the artichoke (e.g., luteolin) have been shown to prevent LDL-cholesterol oxidation—an effect that may reduce risk of **atherosclerosis** (page 38).<sup>10</sup>

#### How much is usually taken?

The suggested adult amount of the standardized leaf extract is 300–640 mg three times daily for a minimum of six weeks.<sup>11</sup> Alternatively, if a standardized extract is not available, the amount of the crude, dried leaves is 1–4 grams, three times a day.<sup>12</sup>

#### Are there any side effects or interactions?

At the recommended amount and according to the German Commission E Monograph,<sup>13</sup> there are no known side effects or drug interactions. The use of artichoke is not recommended for those who are allergic to artichokes and other members of the Compositae (e.g., daisy) family. In addition, those who have any obstruction of the bile duct (e.g., as a result of **gallstones** [page 193]) should not employ this plant therapeutically. The plant's safety during **pregnancy** (page 363) and breastfeeding has not been established.

## ASHWAGANDHA

**Botanical name:** *Withania somniferum*

#### Parts used and where grown

Ashwagandha, which belongs to the pepper family, is found in India and Africa. The roots of ashwagandha are used medicinally.

**Ashwagandha has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Immune function</b> (page 255)
★☆☆	<b>Osteoarthritis</b> (page 328) Stress

#### Historical or traditional use (may or may not be supported by scientific studies)

The health applications for ashwagandha in traditional Indian and Ayurvedic medicine are extensive. Of particular note is its use against tumors, inflammation (including arthritis), and a wide range of infectious diseases.<sup>1</sup> The shoots and seeds are also used as food and to thicken milk in India. Traditional uses of ashwagandha among tribal peoples in Africa include fevers and inflammatory conditions.<sup>2</sup> Ashwagandha is frequently a constituent of Ayurvedic formulas, including a relatively common one known as shilajit.

#### Active constituents

The constituents believed to be active in ashwagandha have been extensively studied.<sup>3</sup> Compounds known as withanolides are believed to account for the multiple medicinal applications of ashwagandha.<sup>4</sup> These molecules are steroid-like and bear a resemblance, both in their action and appearance, to the active constituents of **Asian ginseng** (page 630) (*Panax ginseng*) known as ginsenosides. Indeed, ashwagandha has been called "Indian ginseng" by some. Ashwagandha and its withanolides have been extensively researched in a variety of animal studies examining effects on **immune function** (page 255), inflammation, and even **cancer** (page 87). Ashwagandha stimulates the activation of immune system cells, such as lymphocytes.<sup>5</sup> It has also been shown to inhibit inflammation<sup>6</sup> and improve memory in animal experiments.<sup>7</sup> Taken together, these actions may support the traditional reputation of ashwagandha as a tonic or adaptogen<sup>8</sup>—an herb with multiple, nonspecific actions that counteract the effects of stress and generally promote wellness.

#### How much is usually taken?

Some experts recommend 3–6 grams of the dried root, taken each day in capsule or tea form.<sup>9</sup> To prepare a tea,  $\frac{3}{4}$ –1½ teaspoons (3–6 grams) of ashwagandha root are boiled for 15 minutes and cooled; 3 cups (750 ml) may be drunk daily. Alternatively, tincture  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (2–4 ml) three times per day, is sometimes recommended.

### Are there any side effects or interactions?

No significant side effects have been reported with ashwagandha. The herb has been used safely by children in India. Its safety during **pregnancy** (page 363) and breastfeeding is unknown.

## ASIAN GINSENG

**Common names:** Korean ginseng, Chinese ginseng

**Botanical name:** *Panax ginseng*

### Parts used and where grown

Asian ginseng is a member of the *Araliaceae* family, which also includes the closely related **American ginseng** (page 625) (*Panax quinquefolius*) and less similar Siberian ginseng (*Eleutherococcus senticosus*), also known as **eleuthero** (page 672). Asian ginseng commonly grows on mountain slopes and is usually harvested in the fall. The root is used, preferably from plants older than six years of age.

**Asian ginseng has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Erectile dysfunction</b> (page 185)
★★☆	<b>Athletic performance</b> (page 43) <b>Diabetes</b> (page 152) <b>Epilepsy</b> (page 183) (in combination with <b>bupleurum</b> [page 647], peony root, pinellia root, cassia bark, <b>ginger</b> [page 680] root, jujube fruit, <b>Chinese scullcap</b> [page 658] root, and <b>licorice</b> [page 702] root) <b>Immune function</b> (page 255) <b>Infertility (male)</b> (page 304)
★☆☆	<b>Aerobic capacity</b> <b>Chronic fatigue syndrome</b> (page 111) <b>Common cold/sore throat</b> (page 129) <b>HIV support</b> (page 239) <b>Infection</b> (page 265) <b>Influenza</b> (page 270) <b>Lung cancer</b> (page 298) <b>Menopause</b> (page 311) Stress

### Historical or traditional use (may or may not be supported by scientific studies)

Asian ginseng has been a part of Chinese medicine for over 2,000 years. The first reference to the use of Asian

ginseng dates to the 1st century A.D. Ginseng is commonly used by elderly people in the Orient to improve mental and physical vitality.

### Active constituents

Ginseng's actions in the body are thought to be due to a complex interplay of constituents. The primary group are the ginsenosides, which are believed to counter the effects of stress and enhance intellectual and physical performance. Thirteen ginsenosides have been identified in Asian ginseng. Two of them, ginsenosides Rg1 and Rb1, have been closely studied.<sup>1</sup> Other constituents include the panaxans, which may help lower blood sugar, and the polysaccharides (complex sugar molecules), which are thought to support **immune function** (page 255).<sup>2,3</sup>

Long-term intake of Asian ginseng may be linked to a reduced risk of some forms of **cancer** (page 87).<sup>4,5</sup> A double-blind trial found that 200 mg of Asian ginseng per day improved blood sugar levels in people with type 2 (non-insulin-dependent) **diabetes** (page 152).<sup>6</sup> Human trials have mostly failed to confirm the purported benefit of Asian ginseng for the enhancement of **athletic performance** (page 43).<sup>7,8</sup> One preliminary trial suggests it may help those in poor physical condition to tolerate exercise better.<sup>9</sup> In combination with some vitamins and minerals, 80 mg of ginseng per day was found to effectively reduce fatigue in a double-blind trial.<sup>10</sup> Another double-blind trial also found it helpful for relief of fatigue and, possibly, stress.<sup>11</sup> Although there are no human clinical trials, adaptogenic herbs such as Asian ginseng may be useful for people with **chronic fatigue syndrome** (page 111). This may be because these herbs are thought to have an immunomodulating effect and also help support the normal function of the hypothalamic-pituitary-adrenal axis, the hormonal stress system of the body.<sup>12</sup>

Asian ginseng may also prove useful for **male infertility** (page 304). A double-blind trial with a large group of infertile men found that 4 grams of Asian ginseng per day for three months led to an improvement in sperm count and sperm motility.<sup>13</sup>

Asian ginseng may also help men with **erectile dysfunction** (page 185). A double-blind trial in Korea found that 1,800 mg per day of Asian ginseng extract for three months helped improve libido and the ability to maintain an erection in men with erectile dysfunction.<sup>14</sup> This finding was confirmed in another double-blind study, in which 900 mg three times a day was given for eight weeks.<sup>15</sup>

### How much is usually taken?

The most researched form of ginseng, standardized herbal extracts, supply approximately 5–7% ginsenosides.<sup>16</sup> Ginseng root extracts are sometimes recommended at 200–500 mg per day. Non-standardized extracts require a higher intake, generally 1–4 grams per day for tablets or 2–3 ml for dried root tincture three times per day. Ginseng is traditionally used for two to three weeks continuously, followed by a one- to two-week “rest” period before resuming.

### Are there any side effects or interactions?

Used in the recommended amounts, ginseng is generally safe. In rare instances, it may cause over-stimulation and possibly **insomnia** (page 270).<sup>17</sup> Consuming caffeine with ginseng increases the risk of over-stimulation and gastrointestinal upset. People with uncontrolled **high blood pressure** (page 246) should use ginseng cautiously. Long-term use of ginseng may cause menstrual abnormalities and breast tenderness in some women. Ginseng is not recommended for **pregnant** (page 363) or **breast-feeding** (page 74) women.

## ASTRAGALUS

**Common name:** Huang qi

**Botanical name:** *Astragalus membranaceus*

### Parts used and where grown

Astragalus is native to northern China and the elevated regions of the Chinese provinces, Yunnan and Sichuan. The portion of the plant used medicinally is the four-to seven-year-old dried root, collected in the spring. While over 2,000 types of astragalus exist worldwide, the Chinese version has been extensively tested, both chemically and pharmacologically.<sup>1</sup>

**Astragalus has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Common cold/sore throat</b> (page 129) <b>Heart attack</b> (page 212) <b>Hepatitis</b> (page 220) <b>Immune function</b> (page 255) <b>Infection</b> (page 265) <b>Systemic lupus erythematosus</b> (page 421)

### Historical or traditional use (may or may not be supported by scientific studies)

Shen Nung, the founder of Chinese herbal medicine, classified astragalus as a superior herb in his classical treatise *Shen Nung Pen Tsao Ching* (circa A.D. 100). The Chinese name *huang qi* translates as “yellow leader,” referring to the yellow color of the root and its status as one of the most important tonic herbs. Traditional Chinese Medicine used this herb for night sweats, deficiency of chi (e.g., fatigue, weakness, and loss of appetite), and **diarrhea** (page 163).<sup>2</sup>

### Active constituents

Astragalus contains numerous components, including **flavonoids** (page 516), polysaccharides, triterpene glycosides (e.g., astragalosides I–VII), **amino acids** (page 465), and trace minerals.<sup>3</sup> Several preliminary clinical trials in China have suggested that astragalus can benefit **immune function** (page 255) and improve survival in some people with **cancer** (page 87).<sup>4</sup> Given the poor quality of these trials, it is difficult to know how useful astragalus really was. One Chinese trial also found that astragalus could decrease overactive immune function in people with **systemic lupus erythematosus** (page 421) (SLE), an autoimmune disease.<sup>5</sup> Further trials are needed, however, to know if astragalus is safe for people with SLE, or any other autoimmune disease.

A double-blind trial found that, in people undergoing dialysis for kidney failure, intravenous astragalus improved one facet of immune function compared to the immune function of untreated people.<sup>6</sup> Further study is needed to determine if astragalus can help prevent **infections** (page 265) in people undergoing dialysis. Early clinical trials in China suggest astragalus root might also benefit people with chronic viral **hepatitis** (page 220), though it may take one to two months to see results.<sup>7</sup>

In preliminary trials in China, astragalus has been used after people suffer **heart attacks** (page 212).<sup>8</sup> More research is needed to determine whether astragalus is truly beneficial in this situation.

### How much is usually taken?

Textbooks on Chinese herbs recommend taking 9–15 grams of the crude herb per day in decoction form.<sup>9</sup> A decoction is made by boiling the root in water for a few minutes and then brewing the tea. Alternatively, 3–5 ml of tincture three times per day, are sometimes recommended.

### **Are there any side effects or interactions?**

Astragalus has no known side effects when used as recommended.

## **BACOPA**

**Common names:** Brahmi, water hyssop

**Botanical name:** *Bacopa monniera*

### **Parts used and where grown**

Bacopa is native to India, where it grows in marshy areas. In the West, bacopa is a familiar water plant used in aquariums. Most parts of the plant have been used traditionally, but modern preparations are extracts of the stem and leaves.

**Bacopa has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Alzheimer's disease</b> (page 19)
	<b>Anxiety</b> (page 30)
	<b>ARCD</b> (page 8)
	<b>Epilepsy</b> (page 183)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Since at least the sixth century A.D., bacopa (Brahmi) has been used in Ayurvedic medicine (the traditional medicine of India) as a diuretic and as a tonic for the nervous system and the heart. Specific uses include the treatment of asthma, insanity, and epilepsy.<sup>1</sup>

### **Active constituents**

The leaves of bacopa contain saponins, including the bacosides,<sup>2, 3, 4</sup> which are thought responsible for the therapeutic properties of the herb. In animal studies, both purified bacosides and extracts of bacopa standardized for bacosides have been found to enhance several aspects of mental function and learning ability.<sup>5, 6, 7</sup> Additional brain effects of bacopa demonstrated in animal research include reduction of both anxiety and depression.<sup>8, 9</sup> Biochemically, these nervous-system effects have been attributed to an enhancement of the effects of the neurotransmitters acetylcholine and,<sup>10, 11</sup> possibly, serotonin or GABA (gamma aminobutyric acid).<sup>12, 13</sup>

Bacopa extracts also appear to have significant antioxidant activity in the brain,<sup>14</sup> and other effects that may help protect brain cells.<sup>15</sup>

Animal research has also reported that bacopa extracts can relax the muscles that control the blood vessels, the intestine, and the airways of the respiratory system,<sup>16, 17, 18, 19</sup> and can help both prevent and heal ulcers in the stomach.<sup>20</sup>

Traditional herbal references recommend 5 to 10 grams per day of the powdered herb.<sup>21</sup> Human research has used 300 to 450 mg per day of an extract standardized to contain 55% bacosides.

Bacopa appears to be well tolerated when taken in typical amounts,<sup>22</sup> although one double-blind study reported significantly more symptoms of dry mouth, nausea, and muscle fatigue in participants taking bacopa.<sup>23</sup>

## **BARBERRY**

**Botanical name:** *Berberis vulgaris*

### **Parts used and where grown**

The root and stem bark contain the medicinally active components of barberry. The barberry bush also produces small red berries. Although this particular species is native to Europe, it now also grows throughout North America. A closely related species, **Oregon grape** (page 721) (*Berberis aquifolium*), is native to North America.

**Barberry has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Chronic candidiasis</b> (page 109)
	<b>Diarrhea</b> (page 163) (berberine)
	<b>Indigestion</b> (page 260)
	<b>Infection</b> (page 265)
	<b>Parasites</b> (page 343)
	<b>Psoriasis</b> (page 379)
	<b>Vaginitis</b> (page 438)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Traditionally, in European and American herbalism, barberry was used to treat a large number of conditions,

particularly **infections** (page 265) and stomach problems.<sup>1</sup> It has also been used internally to treat skin conditions.

### Active constituents

The alkaloid, berberine, receives the most research and widest acclaim as the active component of barberry and its relatives. Berberine is also a key constituent of **goldenseal** (page 683) (*Hydrastis canadensis*). Berberine and its related constituents (such as oxyacanthine) are anti-bacterial<sup>2</sup> and have been shown to kill amoebae in a test tube study.<sup>3</sup> Berberine inhibits bacteria from attaching to human cells, which helps prevent **infection** (page 265).<sup>4</sup> This compound treats **diarrhea** (page 163) caused by bacteria, such as *E. coli*.<sup>5</sup> Berberine also stimulates some **immune system cells** (page 255) to function better.<sup>6</sup> Berbamine is another alkaloid found in barberry. It may help reduce inflammation<sup>7</sup> and is an **antioxidant** (page 467).<sup>8</sup>

The bitter compounds in barberry, including the alkaloids mentioned above, stimulate digestive function following meals.

### How much is usually taken?

For digestive conditions, barberry is often combined with other bitter herbs, such as **gentian** (page 680), in tincture form. Such mixtures are taken 15 to 20 minutes before a meal, usually 2–5 ml each time. As a tincture, 2–3 ml of barberry can be taken three times per day. Standardized extracts containing 5–10% alkaloids, with a total of approximately 500 mg of berberine taken each day, are preferable for preventing **infections** (page 265). Standardized extracts of **goldenseal** (page 683) are a more common source of berberine, since goldenseal contains a higher concentration of berberine than barberry. An ointment made from a 10% extract of barberry can be applied topically three times per day for **psoriasis** (page 379). A tea/infusion can be prepared using 2 grams of the herb in a cup of boiling water. This can be repeated two to three times daily.<sup>9</sup>

### Are there any side effects or interactions?

Berberine has been reported to interfere with normal liver function in infants, raising a concern that it might worsen jaundice.<sup>10</sup> For this reason, berberine-containing plants, including barberry, goldenseal, and Oregon grape should be used with caution during **pregnancy** (page 363) and breast-feeding. Strong standardized extracts may cause stomach upset and should be used for

no more than two weeks continuously. Other symptoms of excessive berberine intake include lethargy, nose bleed, skin and eye irritation, and kidney irritation.<sup>11</sup>

## BASIL

**Common names:** Common basil, sweet basil

**Botanical name:** *Ocimum basilicum*

### Parts used and where grown

The leaves of basil and its many close relatives are used as medicine. The seeds are also used medicinally in India and Southeast Asia. Though it originates on the shores of the Mediterranean Sea and the Middle East, common basil now grows in gardens all over the world. Three important relatives with similar properties are *Ocimum canum* (hairy basil), *O. gratissimum* (basil), and *O. sanctum* (holy basil).

**Basil has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Constipation</b> (page 137) <b>Diabetes</b> (page 152)
★☆☆	<b>Indigestion</b> (page 260)

### Historical or traditional use (may or may not be supported by scientific studies)

Basil has been a culinary herb in Europe and Central Asia since before the written word.<sup>1</sup> In India the seeds were used for **diarrhea** (page 163), mucous discharges, **constipation** (page 137), and as a general demulcent (soothes mucous membranes);<sup>2</sup> the leaves were used for **indigestion** (page 260) and skin diseases. In traditional Thai herbalism, the plant is used for **coughs** (page 139), skin diseases, and intestinal problems. The seed is used as a bulk-forming laxative and diuretic.<sup>3</sup>

### Active constituents

Basil contains a strong-scented volatile oil composed primarily of terpenoids, particularly eugenol, thymol, and estragole. Basil also has what are known as chemotypes, minor variations among plants that con-

tain significantly different mixes of constituents. The exact components of basil oil vary widely, being affected not only by these chemotypes but also by factors such as the time of day of harvest.<sup>4</sup> This may account for some of the variability in scientific research and reports of medicinal efficacy of basil from culture to culture.

Preliminary studies on holy basil and hairy basil have shown that the leaf and seed may help people with type 2 **diabetes** (page 152) control their blood sugar levels.<sup>5, 6, 7</sup> While the action-mechanism of the leaf is not understood, the seed may work by providing dietary **fiber** (page 512), which helps prevent rapid blood sugar elevations after meals. In addition, the seed has been found to relieve **constipation** (page 137) by acting as a bulk-forming laxative in one uncontrolled human study.<sup>8</sup> A similar study showed the seeds useful in elderly people who experienced constipation after undergoing major surgery.<sup>9</sup>

The volatile oil of basil has shown antibacterial, anti-fungal, and antiviral activity in test tube studies.<sup>10</sup> It is also believed to act as a carminative, relieving **intestinal gas** (page 260), and as a mild diuretic, though these actions have yet to be definitively proven.<sup>11</sup>

#### **How much is usually taken?**

A tea can be made by steeping 1 teaspoon of basil leaves in one cup of water for ten minutes. Three cups of this tea can be drunk per day. Capsules of basil can be taken in the amount of 2.5 grams per day. The volatile oil can be taken internally in the amount of 2 to 5 drops three times per day.<sup>12</sup>

#### **Are there any side effects or interactions?**

Although concerns have been raised about the possible cancer-causing effects of estragole, a component found in variable amounts in basil volatile oil, small amounts of basil would not seem to pose a significant threat.<sup>13</sup> However, because some herbal books suggest that estragole may be potentially carcinogenic and has been thought to stimulate uterine contractions, some herbal experts feel it may be best for **pregnant** (page 363) or **breast-feeding** (page 74) women to avoid use of the herb, especially the volatile oil.<sup>14</sup> People with serious kidney or liver damage should not use basil volatile oil internally, as they could theoretically have trouble eliminating it from their bodies. However, use of basil as a seasoning in food is unlikely to be of concern.

## BILBERRY

**Botanical name:** *Vaccinium myrtillus*

#### **Parts used and where grown**

A close relative of American **blueberry** (page 641), bilberry grows in northern Europe, Canada, and the United States. The ripe berries are primarily used in modern herbal extracts.

**Bilberry has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Diabetes</b> (page 152) <b>Retinopathy</b> (page 385)
★☆☆	<b>Atherosclerosis</b> (page 38) <b>Cataracts</b> (page 101) <b>Diarrhea</b> (page 163) <b>Macular degeneration</b> (page 303) <b>Night blindness</b> (page 326)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

The dried berries and leaves of bilberry have been recommended for a wide variety of conditions, including scurvy, **urinary tract infections** (page 436), **kidney stones** (page 284), and **diabetes** (page 152). Perhaps the most sound historical application is the use of the dried berries to treat **diarrhea** (page 163). Modern research of bilberry was partly based on its use by British World War II pilots, who noticed that their night vision improved when they ate bilberry jam prior to night bombing raids.<sup>1</sup>

#### **Active constituents**

Anthocyanosides, the **flavonoid** (page 516) complex in bilberries, speed the regeneration of rhodopsin, the purple pigment that is used by the rods in the eye for night vision.<sup>2</sup> While earlier trials suggested that taking bilberry could benefit people with **night blindness** (page 326),<sup>3, 4</sup> more recent trials with healthy volunteers have found no effect of bilberry on night vision.<sup>5, 6</sup> Preliminary human trials conducted in Europe show that bilberry may prevent **cataracts** (page 101),<sup>7</sup> and may even help to treat people with mild retinopathies (such as **macular degeneration** [page 303] and diabetic

**retinopathy** [page 385]).<sup>8,9</sup> Anthocyanosides are potent **antioxidants** (page 467).<sup>10</sup> They support normal formation of connective tissue and strengthen capillaries in the body. Anthocyanosides may also improve capillary and venous blood flow. Bilberry may also prevent blood vessel thickening due to **diabetes** (page 152).<sup>11</sup>

Bilberry protects cholesterol from oxidizing in test tubes.<sup>12</sup> While this action is thought to help prevent **atherosclerosis** (page 38), no human trials have studied whether bilberry may be useful in the regard.

#### How much is usually taken?

Bilberry herbal extract in capsules or tablets standardized to provide 25% anthocyanosides are typically recommended at 240–600 mg per day.<sup>13</sup> Herbalists have traditionally recommended taking 1–2 ml two times per day in tincture form, or 20–60 grams of the fruit daily.

#### Are there any side effects or interactions?

In recommended amounts, no side effects have been reported with bilberry extract.

## BITTER MELON

**Botanical name:** *Momordica charantia*

#### Parts used and where grown

Bitter melon grows in tropical areas, including parts of East Africa, Asia, the Caribbean, and South America, where it is used as a food as well as a medicine. The fruit of this plant lives up to its name—it tastes bitter. Although the seeds, leaves, and vines of bitter melon have all been used, the fruit is the safest and most prevalent part of the plant used medicinally.

**Bitter melon has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Diabetes</b> (page 152)
★★☆	<b>Indigestion</b> (page 260)

#### Historical or traditional use (may or may not be supported by scientific studies)

Being a relatively common food item, bitter melon was traditionally used for an array of conditions by people in tropical regions. Numerous **infections** (page 265), **can-**

**cer** (page 87), and **diabetes** (page 152) were among the most common conditions it has been purported to improve.<sup>1</sup> The leaves and fruit have both been used in the Western world to make teas and beer or to season soups.

#### Active constituents

At least three different groups of constituents in bitter melon have been reported to have blood-sugar lowering actions of potential benefit in **diabetes** (page 152) mellitus. These include a mixture of steroid saponins known as charantin, insulin-like peptides, and alkaloids. It is still unclear which of these is most effective, or if all three work together. Some clinical trials have confirmed the benefit of bitter melon for people with diabetes.<sup>2</sup>

In traditional herbal medicine, bitter melon—like other bitter-tasting herbs—is thought to stimulate digestive function and improve appetite. This has yet to be tested in human studies.

#### How much is usually taken?

For those with a taste or tolerance for bitter flavor, a small melon can be eaten as food, or up to 3 1/3 ounces (100 ml) of a decoction or 2 ounces (60 ml) of fresh juice can be drunk per day.<sup>3</sup> Though still bitter, tinctures of bitter melon (1 teaspoon [5 ml] two to three times per day) are also sometimes used. The amounts recommended would be appropriate for people with **diabetes** (page 152).

#### Are there any side effects or interactions?

Ingestion of excessive amounts of bitter melon juice (several times more than the amount recommended above) can cause abdominal pain and **diarrhea** (page 163).<sup>4</sup> Excessive ingestion of the seeds had been associated with headache, fever, and coma. Bitter melon is not recommended for **pregnant** (page 363) women. People with **hypoglycemia** (page 251) (low blood sugar) should not take bitter melon, because it may trigger or worsen the problem. This effect has been reported in two young children and one adult patient with **diabetes** (page 152).

## BITTER ORANGE

**Common names:** Seville orange, zhi shi, chongcao

**Botanical name:** *Citrus X aurantium*

#### Parts used and where grown

The dried outer peel of the fruit of bitter orange, with the white pulp layer removed, is used medicinally. The

leaves are also commonly used in many folk traditions. The bitter orange tree is indigenous to eastern Africa, Arabia, and Syria, and cultivated in Spain, Italy, and North America.

**Bitter orange has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Indigestion</b> (page 260) Loss of appetite
★★★	<b>Insomnia</b> (page 270) <b>Weight loss</b> (page 446)

**Historical or traditional use (may or may not be supported by scientific studies)**

Bitter orange is used similarly in a wide variety of traditions. In Mexico and South America the leaf is used as a tonic, as a laxative, as a sedative for insomnia, and to calm frazzled nerves.<sup>1,2</sup> The peel of the fruit is used for stomach aches and high blood pressure.<sup>3,4</sup> The Basque people in Europe use the leaves for stomach aches, insomnia, and palpitations and the bitter orange peel as an anti-spasmodic.<sup>5</sup> In traditional Chinese medicine, the peel of the immature fruit is used for indigestion, abdominal pain, constipation, and dysenteric diarrhea. Where the patient is weak, the milder, mature fruit is used similarly.<sup>6</sup> Bitter orange continues to be widely used for insomnia and indigestion in many parts of the world.<sup>7</sup>

**Active constituents**

Bitter orange has a complex chemical makeup, though it is perhaps most known for the volatile oil in the peel. The familiar oily residue that appears after peeling citrus fruit, including bitter orange, is this volatile oil. It gives bitter orange its strong odor and flavor, and accounts for many of its medicinal effects. Besides the volatile oil, the peel contains flavones, the alkaloids synephrine, octopamine, and N-methyltyramine, and carotenoids.<sup>8,9</sup>

**How much is usually taken?**

Usually 1 to 2 grams of dried peel is simmered for 10 to 15 minutes in a cup of water; three cups are drunk daily. As a tincture, 2 to 3 ml (with a weight-to-volume ratio ranging from 1:1 to 1:5) is often recommended

for use three times per day.<sup>10</sup> The purified volatile oil is generally avoided for reasons discussed in the side effects section.

**Are there any side effects or interactions?**

Bitter orange oil may possibly cause light sensitivity (photosensitivity), especially in fair-skinned individuals.<sup>11</sup> Generally this occurs only if the oil is applied directly to the skin and then exposed to bright light; in rare cases it has also been known to occur in people who have taken bitter orange internally. The oil should not be applied topically and anyone who uses it internally should avoid bright light, including tanning booths.

Internal use of the volatile oil of bitter orange is also potentially unsafe and should not be undertaken without expert guidance. Large amounts of orange peel have caused intestinal colic, convulsions, and death in children.<sup>12</sup> The amounts recommended above for internal use should not be exceeded.

One text on Chinese medicine cautions against the use of bitter orange in pregnancy.<sup>13</sup> This concern is not raised in any other reference, and the American Herbal Products Association classifies the herb as “class 1,” an herb that can be safely consumed during pregnancy when used appropriately.<sup>14</sup>

Decoctions of bitter orange substantially increased blood levels of cyclosporine in pigs, causing toxicity.<sup>15</sup> Bitter orange also inhibited human cytochrome P450 3A (CYP3A) in the test tube.<sup>16</sup> This is an enzyme that helps the liver get rid of numerous toxins, and strongly affects metabolism of certain drugs. Bitter orange might, therefore, interact with drugs that are metabolized by CYP3A. To be on the safe side, bitter orange should not be combined with prescription medications, unless someone is under the care of an experienced natural medicine clinician.

## BLACKBERRY

**Common names:** Dewberry, European blackberry

**Botanical name:** *Rubus fruticosus*

**Parts used and where grown**

Blackberries grow in wet areas across the United States and Europe. Several species of blackberry exist: *Rubus fruticosus* is the most common European species and

*Rubus canadensis* is a common North American species. While the leaves are used most frequently for medicinal preparations, the root is sometimes used as well.

**Blackberry has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Common cold/sore throat</b> (page 129) <b>Diarrhea</b> (page 163)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Since ancient Greek physicians prescribed blackberry for **gout** (page 208), the leaves, roots, and even berries have been used as herbal medicines.<sup>1</sup> The most common uses were for treating **diarrhea** (page 163), **sore throats** (page 129), and **wounds** (page 319). These are similar to the uses of its close cousin, the **red raspberry** (page 735) (*Rubus idaeus*), and a somewhat more distant relative, the **blueberry** (page 641) (*Vaccinium corymbosum*).

#### **Active constituents**

The presence of large amounts of tannins give blackberry leaves and roots an astringent effect that may be useful for treating **diarrhea** (page 163).<sup>2</sup> These same constituents may also be helpful for soothing **sore throats** (page 129).

#### **How much is usually taken?**

The German Commission E monograph recommends 4.5 grams of blackberry leaf per day.<sup>3</sup> Blackberry tea is prepared by adding 1.5 grams of leaves or powdered root to 250 ml of boiling water and allowing it to steep for 10 to 15 minutes. Three cups per day should be drunk. Alternatively, one may use 3–4 ml of tincture three times each day.

#### **Are there any side effects or interactions?**

Tannins can cause nausea and even vomiting in people with sensitive stomachs. People with chronic gastrointestinal problems might be particularly at risk for such reactions. Taking blackberry leaf or root preparations with food may reduce risk of gastrointestinal problems in some people.

## BLACK COHOSH

**Botanical name:** *Cimicifuga racemosa*

#### **Parts used and where grown**

Black cohosh is a shrub-like plant native to the eastern deciduous forests of North America, ranging from southern Ontario to Georgia, north to Wisconsin and west to Arkansas. The dried root and rhizome are used medicinally.<sup>1</sup> When harvested from the wild, the root is black in color. Cohosh, an Algonquin Indian word meaning “rough,” refers to the plants gnarly root structure.<sup>2</sup>

**Black cohosh has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Menopause</b> (page 311)
★☆☆	<b>Dysmenorrhea</b> (page 171) (painful menstruation) <b>Osteoporosis</b> (page 333) <b>Premenstrual syndrome</b> (page 368)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Native Americans valued the herb and used it for many conditions, ranging from gynecological problems to rattlesnake bites. Some 19th century American physicians used black cohosh for fever, menstrual cramps, arthritis, and **insomnia** (page 270).<sup>3</sup>

#### **Active constituents**

Black cohosh contains several ingredients, including triterpene glycosides (e.g., acetin and 27-deoxyactein) and isoflavones (e.g., formononetin). Other constituents include aromatic acids, tannins, resins, fatty acids, starches, and sugars. As a woman approaches **menopause** (page 311), the signals between the ovaries and pituitary gland diminish, slowing down estrogen production and increasing luteinizing hormone (LH) secretions. Hot flashes can result from these hormonal changes. Earlier animal studies<sup>4, 5</sup> and a human clinical trial<sup>6</sup> suggested that black cohosh had some estrogen activity in the body and also decreased LH secretions. However, more recent animal studies<sup>7</sup> and a clinical

trial<sup>8</sup> have found no estrogen activity for black cohosh extracts. Further clinical trials are needed to determine whether black cohosh has significant estrogenic actions in the body.

Small German clinical trials support the usefulness of black cohosh for women with hot flashes associated with menopause.<sup>9, 10</sup> A review of eight clinical trials found black cohosh to be both safe and effective for symptomatic relief of menopausal hot flashes.<sup>11</sup> Other symptoms which improved included night sweats, **insomnia** (page 270), nervousness, and irritability. A clinical trial compared the effects of 40 mg versus 130 mg of black cohosh in menopausal women with complaints of hot flashes.<sup>12</sup> While hot flashes were reduced equally at both amounts, there was no evidence of any estrogenic effect in any of the women. Although further trials are needed, this trial suggests that black cohosh is best reserved only for the symptomatic treatment of hot flashes associated with menopause and is not thought to be a substitute for hormone replacement therapy in menopausal and postmenopausal women.

A recent study suggests black cohosh may protect animals from **osteoporosis** (page 333).<sup>13</sup> Human studies have not confirmed this action.

### How much is usually taken?

Black cohosh can be taken in several forms, including crude, dried root or rhizome (300–2,000 mg per day), or as a solid, dry powdered extract (250 mg three times per day). Standardized extracts of the herb are available. The recommended amount is 20–40 mg twice per day.<sup>14</sup> The best researched extract provides 1 mg of deoxyactein per 20 mg of extract. Tinctures can be taken at 2–4 ml three times per day.<sup>15</sup> Black cohosh can be taken for up to six months, and then it should be discontinued.<sup>16</sup>

### Are there any side effects or interactions?

Black cohosh should not be used by **pregnant** (page 363) or **breast-feeding women** (page 74).<sup>17</sup> Very large amounts (over several grams daily) of this herb may cause abdominal pain, nausea, headaches, and dizziness. There is one case report of a woman developing autoimmune hepatitis while using black cohosh.<sup>18</sup> A cause–effect relationship is in doubt, however, because the hepatitis did not resolve after black cohosh was discontinued. A few cases have also been reported in which severe liver failure was attributed to the use of black cohosh.<sup>19</sup> While a cause–effect relationship is difficult to prove, and while such a side effect appears to

be rare, people taking black cohosh should be alert to signs of possible liver disease, such as nausea, loss of appetite, fatigue, and tan-colored urine. Black cohosh is not a substitute for hormone replacement therapy during **menopause** (page 311).

## BLACK HOEHOUND

**Botanical name:** *Ballota nigra*

### Parts used and where grown

This European mint family (Lamiaceae) plant now grows in North America and on other continents as well. The leaf and flower are used medicinally. This plant should not be confused with **white horehound** (page 691), which acts differently.

**Black horehound has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Motion sickness</b> (page 322) Nausea

### Historical or traditional use (may or may not be supported by scientific studies)

Black horehound has primarily been used in European traditional herbalism to relieve nausea, **anxiety** (page 30), or the combination of these conditions.<sup>1</sup> It was also used as a mild expectorant and to help normalize menstruation.

### Active constituents

Phenylpropanoids—flavonoids and compounds found in the volatile oil of black horehound—are believed to be the plant's major active constituents.<sup>2, 3</sup> A recent test tube study found black horehound phenylpropanoids to have both **antioxidant** (page 467) properties and a sedating effect on overactive nerve cells.<sup>4</sup> Although no human studies have been conducted with black horehound, the herb is believed to be useful for treating nausea associated with **motion sickness** (page 322) due to a possible effect on the central nervous system.<sup>5</sup>

### How much is usually taken?

Black horehound is traditionally used as a tea or tincture. Approximately 2 teaspoons of the leaves are added

to 1 cup hot water and allowed to steep for 10 to 15 minutes.<sup>6</sup> One cup is drunk three times per day. If a tincture is preferred, 1 to 2 ml may be taken three times per day. Black horehound is rarely used alone, and is frequently combined with **meadowsweet** (page 709), **chamomile** (page 656), or **ginger** (page 680) for relief of nausea.

#### **Are there any side effects or interactions?**

There are no reports of adverse effects from use of black horehound when taken in the amounts listed above. Black horehound was traditionally used to treat **nausea during pregnancy** (page 363), though no scientific evaluation of the safety or efficacy of this practice has been conducted. Some sources report that black horehound could induce miscarriage when taken in large amounts.<sup>7</sup> Consult with a doctor who is trained in botanical medicine before using horehound during pregnancy.

## BLADDERWRACK

**Botanical name:** *Fucus vesiculosus*

#### **Parts used and where grown**

Bladderwrack is a type of brown algae (seaweed) that grows on the northern Atlantic and Pacific coasts of the United States and on the northern Atlantic coast and Baltic coast of Europe. The main stem of bladderwrack, known as the thallus, is used medicinally. The thallus has tough, air-filled pods or bladders to help the algae float—thus the name bladderwrack. Although bladderwrack is sometimes called kelp, that name is not specific to this species and should be avoided.

**Bladderwrack has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Constipation</b> (page 137) <b>Diarrhea</b> (page 163) <b>Gastritis</b> (page 195) <b>Gastroesophageal Reflux Disease</b> (page 198) (GERD) <b>Heartburn</b> (page 260) <b>Hypothyroidism</b> (page 252) <b>Indigestion</b> (page 260) Iodine deficiency <b>Wound healing</b> (page 319) (topical)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Bladderwrack's mucilaginous thallus has long been used to soothe irritated and inflamed tissues in the body.<sup>1</sup> It was also historically used as a bulk-forming laxative.<sup>2</sup> People living near oceans or seas have a historically low rate of **hypothyroidism** (page 252), due, in part, to ingestion of iodine-rich food, such as seafood and seaweeds like bladderwrack. It has also been used to counter **obesity** (page 446), possibly due to its reputation for stimulating the thyroid gland. Clinical research in this area has failed to confirm that seaweeds like bladderwrack help with weight loss,<sup>3</sup> though more specific research is warranted.

#### **Active constituents**

There are three major active constituents in bladderwrack: **iodine** (page 538), alginic acid, and fucoidan.

The amount of iodine in bladderwrack is highly variable,<sup>4</sup> probably as a result of different amounts of iodine in the water where it grows. A reasonable portion of bladderwrack may contain the U.S. adult recommended dietary allowance (RDA) of iodine (150 mcg). The RDA amount of iodine is believed to be necessary for maintenance of normal thyroid function in adults (infants and children need proportionally less). Thus, in people with insufficient iodine in their diet, bladderwrack may serve as a supplemental source of iodine. Either **hypothyroidism** (page 252) or **goiter** (page 206) due to insufficient intake of iodine may possibly improve with bladderwrack supplementation, though human studies have not confirmed this.

Alginic acid is a type of dietary **fiber** (page 512) that can be used to help relieve **constipation** (page 137) and **diarrhea** (page 163). However, human studies have not been done on how effective bladderwrack is for either of these conditions. An over-the-counter antacid, Gaviscon, containing magnesium carbonate and sodium alginate (the sodium salt of alginic acid), has been shown to effectively relieve the symptoms of **heartburn** (page 260) compared to other antacids in a double-blind study.<sup>5</sup> However, bladderwrack has not been studied for use in people with heartburn. Bladderwrack might also help indigestion, though again clinical trials have not been conducted. Calcium alginate (the calcium salt of alginic acid) has shown promise as an agent to speed **wound healing** (page 319) in animal studies<sup>6</sup> but has not been demonstrated to be effective in humans.

Alginic acid has also been shown to inhibit **HIV** (page 239) in the test tube.<sup>7</sup> However, this effect has

not been studied in humans. Alginic acid may help lower LDL (“bad”) **cholesterol** (page 223) levels, according to animal studies.<sup>8</sup> No human trials have studied this effect of bladderwrack. It is widely used in food and pharmaceuticals as a thickener and gelling agent.<sup>9</sup>

Fucoidan is another type of dietary fiber in bladderwrack that contains numerous sulfur groups. According to test tube and animal studies, this appears to give fucoidan several properties, such as lowering LDL cholesterol levels,<sup>10</sup> lowering blood glucose levels,<sup>11</sup> anti-inflammatory activity,<sup>12</sup> possible anticoagulant effects,<sup>13</sup> and antibacterial<sup>14</sup> and anti-HIV activity.<sup>15</sup> Though it has not been definitively proven, fucoidan is thought to prevent bacteria and viruses from binding to human cells, a necessary step in starting an **infection** (page 265), as opposed to killing the microbes directly.<sup>16, 17</sup> To date, no human clinical trials have been done with fucoidan or bladderwrack to support their use for any of these conditions.

#### How much is usually taken?

For short-term use (a few days) to relieve **constipation** (page 137), powdered bladderwrack can be taken in the amount of 1 teaspoon three times per day along with at least 8 oz of water each time.<sup>18</sup> For **thyroid problems** (page 252), **gastritis** (page 195), or **heartburn** (page 260), 5 to 10 grams of dried bladderwrack in capsules three times per day has been recommended. Alternately, bladderwrack may be eaten whole or made into a tea using 1 teaspoon per cup of hot water, allowing each cup to sit at least 10 minutes before drinking. Three cups per day of tea can be drunk. No more than 150 mcg **iodine** (page 538) should be consumed from all sources, including bladderwrack, per day.<sup>19</sup> However, most bladderwrack products do not give any indication of their iodine content. Therefore, anyone considering taking bladderwrack should first consult a physician trained in nutrition and herbal medicine.

#### Are there any side effects or interactions?

Bladderwrack is generally safe, though there are three potential problems with its consumption: **acne** (page 4), thyroid dysfunction, and heavy-metal contamination. Iodine in any form—including from bladderwrack and other seaweeds—can cause or aggravate acne in some people.<sup>20</sup> Excessive iodine ingestion can cause either hypothyroidism or hyperthyroidism and should be avoided.<sup>21, 22</sup> Bladderwrack and other seaweeds that grow in heavy-metal-contaminated waters may contain high levels of these toxins (particularly arsenic and

lead), leading to nerve damage,<sup>23</sup> kidney damage,<sup>24</sup> or other problems. Only bladderwrack known to have been harvested from clean water or labeled to indicate the absence of heavy metals or other contaminants should be consumed. The safety of using bladderwrack during **pregnancy** (page 363) and **breast-feeding** (page 74) is unknown. People who are allergic to iodine may need to avoid bladderwrack.

## BLESSED THISTLE

**Botanical name:** *Cnicus benedictus*

#### Parts used and where grown

Although native to Europe and Asia, blessed thistle is now cultivated in many areas of the world, including the United States. The leaves, stems, and flowers are all used in herbal preparations.

**Blessed thistle has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Indigestion and heartburn</b> (page 260) Poor appetite

#### Historical or traditional use (may or may not be supported by scientific studies)

Folk medicine used blessed thistle tea for digestive problems, including gas, **constipation** (page 137), and stomach upset. This herb was also used—like its well-known relative, **milk thistle** (page 710)<sup>1</sup>—for liver and gallbladder diseases.

#### Active constituents

The sesquiterpene lactones, such as cnicin, provide the main beneficial effects of blessed thistle in the treatment of **indigestion** (page 260). The bitterness of these compounds stimulates digestive activity, including the flow of saliva and secretion of gastric juice, which leads to improved appetite and digestion.<sup>2</sup> Some pharmacological evidence suggests that blessed thistle may also have anti-inflammatory properties.<sup>3</sup>

#### How much is usually taken?

The German Commission E monograph recommends 4–6 grams of blessed thistle per day.<sup>4</sup> Alternatively, tinc-

ture ( $\frac{1}{2}$  teaspoon [2 ml] three times per day) may be used. Approximately  $\frac{1}{2}$  teaspoon (2 grams) of the dried herb can also be added to 1 cup (250 ml) of boiling water and steeped 10 to 15 minutes to make a tea. Three cups can be drunk each day.

#### **Are there any side effects or interactions?**

Blessed thistle is generally safe and is not associated with side effects. Anyone with **allergies** (page 14) to plants in the daisy family should use blessed thistle cautiously.

## **BLOODROOT**

**Botanical name:** *Sanguinaria canadensis*

#### **Parts used and where grown**

Bloodroot grows primarily in North America and in India. The rhizomes and root of the plant contain an orange-red latex.

**Bloodroot has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Gingivitis</b> (page 203) (periodontal disease)
★★★	<b>Cough</b> (page 139) <b>Halitosis</b> (page 209) (rinse)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Native Americans employed bloodroot extensively in ritual and medicine. The dye was used as a body paint.<sup>1</sup> **Sore throats** (page 129), **cough** (page 139), rheumatic pains, and various types of **cancer** (page 87) were all treated with bloodroot.

#### **Active constituents**

Alkaloids—principally sanguinarine—constitute the primary active compounds in bloodroot. These are sometimes used in toothpaste and other oral hygiene products because they inhibit the growth of oral bacteria.<sup>2,3</sup> Not all trials have found sanguinaria-containing dental products helpful for gum disease, however.<sup>4</sup>

#### **How much is usually taken?**

Sanguinarine-containing toothpastes and mouth rinses should be used according to manufacturer's directions.

Bloodroot tincture is sometimes included in **cough** (page 139)-relieving formulas, and 10 drops or less may be taken three times per day.<sup>5</sup> However, bloodroot is rarely used alone for this purpose.

#### **Are there any side effects or interactions?**

Although previous studies have suggested the long-term use of dental products containing sanguinarine is safe,<sup>6</sup> a recent report suggests that use of dental preparations containing blood root may be associated with **leukoplakia** (page 289)—a condition characterized by white spots or patches in the mouth that is thought to be pre-cancerous.<sup>7</sup> Only small amounts of bloodroot should be taken internally, since amounts as small as 1 ml (approximately 20–30 drops) of tincture or 1 gram (approximately  $\frac{1}{50}$ th ounce) can cause nausea and vomiting.<sup>8,9</sup>

Long-term use or overdose of bloodroot can also cause stomach pain, **diarrhea** (page 163), visual changes, paralysis, fainting, and collapse.<sup>10</sup> Long-term oral intake of sanguinarine-contaminated cooking oils has been linked in India to **glaucoma** (page 205), **edema** (page 180), **heart disease** (page 98), miscarriage, and diarrhea.<sup>11</sup> The sanguinarine in these cases came from plants other than bloodroot. Nevertheless, bloodroot should not be used long term. The plant is unsafe for use in children and should not be used by **pregnant** (page 363) or lactating women.

Recently the practice of applying ointments containing bloodroot, such as the so-called “black salve,” has been promoted for treatment of skin and other types of **cancer** (page 87).<sup>12</sup> These ointments have never been tested in clinical studies, so their efficacy for treating cancer is unknown. They can cause severe **pain** (page 338), **burns** (page 85), and damage to healthy skin. It is imperative to seek professional diagnosis and treatment for all forms of cancer.

## **BLUEBERRY**

**Botanical name:** *Vaccinium* spp.

#### **Parts used and where grown**

Blueberry is closely related to the European **bilberry** (page 634) (*Vaccinium myrtillus*). Several species of blueberries exist—including *V. pallidum* and *V. corymbosum*—and grow throughout the United States. Blueberry leaves are the primary part of the plant used medicinally. However, the berries are occasionally used.

**Blueberry has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Common cold/sore throat</b> (page 129)
	<b>Diarrhea</b> (page 163)
	<b>Urinary tract infection</b> (page 436)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

According to traditional herbal textbooks, a tea made from blueberry leaves was considered helpful in **diabetes** (page 152), **urinary tract infections** (page 436), and poor appetite.<sup>1</sup> The berries were a prized commodity among the indigenous peoples of North America.

#### **Active constituents**

Tannins make up as much as 10% of blueberry leaves. The astringent nature of tannins likely accounts for the usefulness of blueberry leaf in treating **diarrhea** (page 163).<sup>2</sup> The astringent effect may also be soothing for **sore throats** (page 129).<sup>3</sup> **Bilberry** (page 634), blueberry's European cousin, is used primarily for maintaining blood vessels, particularly those in the eyes. Some preliminary evidence indicates that anthocyanosides, the bioflavonoid complex common to bilberry and blueberry may help people with **diabetes** (page 152), particularly if they have damage to the retina (**retinopathy** [page 385]). However, these studies are primarily based on a standardized extract from bilberry fruit.<sup>4</sup>

#### **How much is usually taken?**

A tea is prepared by combining 1 cup (250 ml) boiling water and 1–2 teaspoons (5–10 grams) of dried leaves and steeping for 15 minutes. As many as 6 cups (1,500 ml) each day may be taken for diarrhea and 3 cups (750 ml) each day for diabetes. Alternatively, 1 teaspoon (5 ml) of tincture can also be used three times per day.

#### **Are there any side effects or interactions?**

If the tea does not significantly reduce diarrhea within two to three days, consult with a healthcare practitioner. Fresh (but not dried) berries tend to be laxative and should be avoided in cases of **diarrhea** (page 163).<sup>5</sup>

## BLUE COHOSH

**Botanical name:** *Caulophyllum thalictroides*

#### **Parts used and where grown**

Blue cohosh grows throughout North America. The roots of this flower are used medicinally. Blue cohosh is not related to **black cohosh** (page 637) (*Cimicifuga racemosa*). However, both herbs are primarily used to treat women's health problems.

#### **Blue cohosh has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Amenorrhea</b> (page 22) (lack of menstruation)
	<b>Dysmenorrhea</b> (page 171) (painful menstruation)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Native Americans are believed to have used blue cohosh flowers to induce labor and menstruation.<sup>1</sup> Blue cohosh is a traditional remedy for lack of menstruation. It is considered an emmenagogue (agent that stimulates menstrual flow) and a uterine tonic. No clinical trials have validated this traditional use. It has also been used traditionally to treat painful periods (**dysmenorrhea** [page 171]). Early-20th-century physicians in the United States who treated with natural remedies (known as Eclectic physicians) used blue cohosh for these same purposes and also to treat kidney infections, arthritis, and other ailments.

#### **Active constituents**

A saponin from blue cohosh called caulosaponin is believed to stimulate uterine contractions.<sup>2</sup> Several other alkaloids may be active in this herb. However, current research about the active constituents of blue cohosh is insufficient.

#### **How much is usually taken?**

Blue cohosh is generally taken as a tincture and should be limited to no more than 1–2 ml taken three times per day. The whole herb (300–1,000 mg per day) is sometimes used. Blue cohosh is generally used in combination with other herbs.

### Are there any side effects or interactions?

Large amounts of blue cohosh can cause nausea, headaches, and **high blood pressure** (page 246). Blue cohosh should only be used under medical supervision and in limited amounts. Using blue cohosh during **pregnancy** (page 363) has been brought into question by reports of an infant developing a stroke and another infant being born with **congestive heart failure** (page 134).<sup>3, 4</sup> Safety studies need to be completed to determine whether blue cohosh is safe to use during pregnancy.

## BLUE FLAG

**Botanical name:** *Iris versicolor*

### Parts used and where grown

The rhizome, or underground stem, of the blue flag (indicating its showy blue flowers) is used medicinally. Blue flag and closely related species (particularly *Iris missouriensis*, western blue flag) grow across North America.

**Blue flag has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Impetigo (topical)

### Historical or traditional use (may or may not be supported by scientific studies)

Based on Native American traditions, Eclectic physicians (19th century doctors who relied on herbs) and herbalists used blue flag for a number of conditions. Of note was its use as a nonspecific **immune enhancer** (page 255), as a laxative, and to detoxify the intestinal tract.<sup>1</sup> Topical application of fresh, sliced rhizomes to the sores of impetigo (a common bacterial skin infection in children) has been recommended by herbalists.<sup>2</sup> Traditional herbalists have used blue flag to treat poor digestion characterized by fat malabsorption.

### Active constituents

The resinous fraction of blue flag contains numerous phenolic glycosides. Traditional herbal texts suggest these constituents stimulate the parasympathetic nervous system, leading to production of bile, saliva, and

sweat.<sup>3</sup> However, modern clinical trials have not confirmed these effects for blue flag.

### How much is usually taken?

Herbalists sometimes recommend up to 10 drops of tincture of the dried rhizome be taken three times per day.<sup>4</sup> The tea form is unlikely to be effective, since the active compounds in blue flag are not water soluble.

### Are there any side effects or interactions?

Blue flag can cause nausea, vomiting, and loose stools if too much is taken.<sup>5</sup> People should not exceed the recommended amount given above. Fresh rhizome should only be applied topically and never taken internally, since it can irritate the mouth<sup>6</sup> and is much more likely to cause nausea and **diarrhea** (page 163). Blue flag should only be taken on the advice of a physician or herbalist trained in its use. Blue flag is unsafe for use during **pregnancy** (page 363) or breast-feeding. People should not give blue flag to children.

## BOLDO

**Botanical name:** *Peumus boldus*

### Parts used and where grown

Boldo is an evergreen shrub or small tree that is native to Chile and is naturalized to the Mediterranean region of Europe. The leaves are used medicinally.<sup>1</sup>

**Boldo has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Indigestion and heartburn (page 260)

### Historical or traditional use (may or may not be supported by scientific studies)

Boldo has a long history of use by the indigenous people of Chile, as a liver tonic and in the treatment of **gallstones** (page 193).

### Active constituents

Boldo contains several types of primary constituents, including volatile oils (e.g., ascaridole, eucalyptol), **flavonoids** (page 516), and alkaloids. Boldine, which

constitutes about one-fourth of the total number of alkaloids present, is the major alkaloid.<sup>2</sup> Scientists believe that boldine is responsible for the plant's choloretic (bile stimulating) and diuretic actions.<sup>3</sup> In conjunction with other herbs, such as **cascara** (page 652), rhubarb, and **gentian** (page 680), boldo has been reported to improve appetite.<sup>4</sup> Ascaridole, a compound found in the volatile oil of the plant, has been used as an anti-parasitic agent but is no longer recommended due its to toxic side effects.<sup>5</sup>

#### How much is usually taken?

Tinctures that are free of ascaridoles are sometimes recommended. People may take 1 ml of tincture three times per day. Volatile oil of boldo is not recommended due to its high ascaridole content.<sup>6,7</sup> The dried leaf can be used as an infusion at 3 grams per day.

#### Are there any side effects or interactions?

The German Commission E monograph<sup>8</sup> suggests that only an ascaridole-free preparation should be used internally. Boldo contains terpene-4-ol, an ingredient similar to that found in **juniper** (page 698), and should be avoided by people with kidney disease, as it could cause kidney irritation.<sup>9</sup> In addition, the herb should not be taken during **pregnancy** (page 363) or breast-feeding. It should also be avoided by people who have obstruction of the liver bile duct, or severe liver disease.<sup>10</sup> Excessive use of the herb over long time periods (more than three to four weeks continuously) is not recommended.

## BONESET

**Botanical name:** *Eupatorium perfoliatum*

#### Parts used and where grown

Boneset belongs to the same botanical family as **echinacea** (page 669) and daisy (*Asteraceae*). It grows primarily in North America. Boneset's leaves and flowering tops are used medicinally.

Boldo

**Boneset has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Common cold/sore throat</b> (page 129) <b>Influenza</b> (page 269)

#### Historical or traditional use (may or may not be supported by scientific studies)

Native Americans used boneset as a treatment for a wide range of infectious and fever-related conditions. Europeans eventually adopted the use of the plant, and extended its traditional uses to include malaria.<sup>1</sup>

#### Active constituents

Boneset contains sesquiterpene lactones, such as eupofolin, eupofolitin, and eufoliatin, as well as polysaccharides and **flavonoids** (page 516). In a test tube study, a particular polysaccharide in boneset was found to stimulate **immune cell function** (page 255).<sup>2</sup> This may partially explain its use to treat minor viral infections, such as **colds** (page 129) and the **flu** (page 269). Boneset also triggers sweating by raising body temperature, potentially of benefit for colds and flu as well.<sup>3</sup>

#### How much is usually taken?

Traditionally, boneset is taken as a tea or tincture. To prepare a tea, boiling water is added to  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–2 grams) of the herb and allowed to steep, covered, for ten to fifteen minutes. Three cups (750 ml) a day may be taken (the tea is quite bitter). Tincture,  $\frac{1}{4}$ – $\frac{3}{4}$  teaspoon (1–4 ml) three times per day, is also often taken.<sup>4</sup>

#### Are there any side effects or interactions?

A small number of people experience nausea and/or vomiting when using boneset. The fresh plant, however, is more likely to cause this than the dried herb. Although potentially liver-damaging chemicals, called pyrrolizidine alkaloids, are found in some plants similar to boneset, the levels in boneset are minimal. There are no known reports of liver damage from taking boneset. Nevertheless, patients with liver disease should avoid boneset, and no one should take it consistently for longer than six months. Boneset is not recommended during **pregnancy** (page 363) or breast-feeding. Boneset should not be used when a high fever (over 102 degrees F) is present.

## BOSWELLIA

**Common name:** Salai guggal

**Botanical name:** *Boswellia serrata*

#### Parts used and where grown

Boswellia is a moderate to large branching tree found in the dry hilly areas of India. When the tree trunk is

tapped, a gummy oleoresin is exuded. A purified extract of this resin is used in modern herbal preparations.

**Boswellia has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Osteoarthritis (page 328)
★★☆	Asthma (page 32) Rheumatoid arthritis (page 387) Ulcerative colitis (page 433)
★☆☆	Bursitis (page 87)

**Historical or traditional use (may or may not be supported by scientific studies)**

In the ancient Ayurvedic medical texts of India, the gummy exudate from boswellia is grouped with other gum resins and referred to collectively as guggals. Historically, the guggals were recommended by Ayurvedic physicians for a variety of conditions, including **osteoarthritis** (page 328), **rheumatoid arthritis** (page 387), **diarrhea** (page 163), dysentery, pulmonary disease, and ringworm.

**Active constituents**

The gum oleoresin consists of essential oils, gum, and terpenoids. The terpenoid portion contains the boswellic acids that have been shown to be the active constituents in boswellia.<sup>1</sup> Today, extracts are typically standardized to contain 37.5–65% boswellic acids.

Studies have shown that boswellic acids have an anti-inflammatory action<sup>2</sup>—much like the conventional nonsteroidal anti-inflammatory drugs (NSAIDs) used for inflammatory conditions. Boswellia inhibits pro-inflammatory mediators in the body, such as leukotrienes.<sup>3</sup> As opposed to NSAIDs, long-term use of boswellia does not appear to cause irritation or ulceration of the stomach. One small, controlled, double-blind trial has shown that boswellia extract may be helpful for **ulcerative colitis** (page 433).<sup>4</sup>

**How much is usually taken?**

The standardized extract of the gum oleoresin of boswellia is recommended by many doctors. For **rheumatoid arthritis** (page 387) or **osteoarthritis** (page 328), 150 mg of boswellic acids are taken three times per day.<sup>5</sup> As an example, if an extract contains 37.5% boswellic acids, 400 mg of the extract would be

taken three times daily. Treatment with boswellia generally lasts eight to twelve weeks. In the one clinical trial to date, people with **ulcerative colitis** (page 433) used 550 mg of boswellia extract three times per day.

**Are there any side effects or interactions?**

Boswellia is generally safe when used as directed. Rare side effects can include **diarrhea** (page 163), skin rash, and nausea. Any inflammatory joint condition should be closely monitored by a physician.

## BUCHU

**Botanical names:** *Barosma betulina*, *Agathosma betulina*, *Agathosma crenulata*

**Parts used and where grown**

Buchu is a low shrub native to the Cape region of South Africa. The dried leaves are harvested during the flowering season. The oil can be obtained by steam distillation of the leaves. The two primary species of buchu used commercially are *Agathosma betulina* (syn. *Barosma betulina*) and *Agathosma crenulata* (syn. *Barosma crenulata*).

**Buchu has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Urinary tract infections and inflammation (page 436)

**Historical or traditional use (may or may not be supported by scientific studies)**

Buchu leaf preparations have a long history of use in traditional herbal medicine as a urinary tract disinfectant and diuretic.<sup>1</sup> Buchu was used by herbalists to treat **urinary tract infections** (page 436) and inflammation, as well as inflammation of the prostate. In Europe, it was also used to treat **gout** (page 208).<sup>2</sup> The original use of buchu by the native peoples of southern Africa is unclear because buchu is a general term for aromatic plants.<sup>3</sup> It appears to have been applied topically, possibly as an insect repellent, and also used internally for stomach problems, rheumatism and bladder problems.

### Active constituents

The leaves of buchu contain 1.0–3.5% volatile oils as well as flavonoids.<sup>4</sup> The urinary tract antiseptic actions of buchu are thought to be due to the volatile oils. The primary volatile oil component thought to have antibacterial action is the monoterpenic disophenol. However, one test tube study using buchu oil found no significant antibacterial effect.<sup>5</sup>

### How much is usually taken?

The German Commission E Monograph concludes there is insufficient evidence to support the modern use of buchu for the treatment of urinary tract infections or inflammation.<sup>6</sup> However, some traditional herbal practitioners continue to recommend the herb for these conditions. Traditional recommendations for the herb include the use of 1–2 grams of the dried leaf taken three times daily in capsules or in a tea.<sup>7</sup> Tinctures can be used at 2–4 ml three times per day.

### Are there any side effects or interactions?

Buchu may cause gastrointestinal irritation and should only be taken with meals. Also, it should not be used by pregnant (page 363) or breast-feeding women.

## BUCKTHORN

**Botanical name:** *Rhamnus catharticus*

### Parts used and where grown

Buckthorn is a tall shrub native to northern Europe. The dried berries and dried bark are used medicinally. The bark is allowed to dry for up to a year before being used, which reduces the potential of buckthorn to cause vomiting.

**Buckthorn has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Constipation (page 137)

### Historical or traditional use (may or may not be supported by scientific studies)

Buckthorn has been used as a cathartic laxative in northern and central Europe, including England, for

centuries.<sup>1</sup> While its importance declined when the similar shrub *Rhamnus purshiana* or *Cascara sagrada* (page 652) was discovered in America,<sup>2</sup> buckthorn is still used, particularly in Europe.

### Active constituents

Buckthorn bark and berries are high in anthraquinone glycosides. Resins, tannins, and lipids make up the bulk of the bark's other ingredients. Buckthorn berries also contain flavonoids. Anthraquinone glycosides have a cathartic action, inducing the large intestine to increase its muscular contraction (peristalsis) and increasing water movement from the cells of the colon into the feces, resulting in strong, soft bowel movement.<sup>3</sup> It takes six to ten hours for buckthorn to act after taking it by mouth.

### How much is usually taken?

Only the dried form of buckthorn berries and bark should be used. Capsules providing 20 to 30 mg of anthraquinone glycosides (calculated as glucofrangulin A) per day can be used; however, the smallest amount necessary to maintain regular bowel movements should be used.<sup>4</sup> As a tincture, 5 ml once at bedtime is generally taken. Usually buckthorn is taken at bedtime, so it will have time to act and by morning a bowel movement is induced. It is important to drink eight six-ounce glasses of water throughout the day while taking buckthorn, and to consume plenty of fresh fruits and vegetables. Buckthorn should be taken for a maximum of eight to ten days consecutively or else it can lead to dependence on it to have a bowel movement.<sup>5</sup> Some people take peppermint tea or capsules with buckthorn to prevent griping, an unpleasant sensation of strong contractions in the colon sometimes induced by buckthorn.

### Are there any side effects or interactions?

Buckthorn may turn the urine dark yellow or red, but this is harmless. Women who are pregnant or breast-feeding and children under the age of 12 should not use buckthorn without the advice of a physician. Those with an intestinal obstruction, **Crohn's disease** (page 141) or any other acute inflammatory problem in the intestines, **diarrhea** (page 163), appendicitis, or abdominal pain should not use this herb.<sup>6</sup> Use or abuse of buckthorn for more than ten days consecutively may cause a loss of electrolytes (especially the mineral potassium) or may weaken the colon. Long-term use can also cause kidney damage.<sup>7</sup>

## BUGLEWEED

**Botanical name:** *Lycopus virginicus*

### Parts used and where grown

The leaves and flowers of this plant from the mint family are used medicinally. Both bugleweed and its European cousin, gypsywort (*Lycopus europaeus*), grow in very wet areas.

**Bugleweed has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Breast pain Hyperthyroidism

### Historical or traditional use (may or may not be supported by scientific studies)

The modern applications of bugleweed, unlike many medicinal plants, do not match its traditional use. Historically, bugleweed and related species were used to treat coughs and as a sedative.<sup>1</sup> Today, the main use of this herb is for treating mild hyperthyroidism.

### Active constituents

Lithospermic acid and other organic acids are believed to be responsible for bugleweed's activity. These acids decrease levels of several hormones in the body, particularly thyroid-stimulating hormones<sup>2</sup> and the thyroid hormone thyroxine (T4).<sup>3</sup> Bugleweed inhibits the binding of antibodies to the thyroid gland.<sup>4</sup> These antibodies can cause the most common form of hyperthyroidism, Graves' disease. All these actions may help explain bugleweed's benefit in people with mildly overactive thyroids.

### How much is usually taken?

The German Commission E monograph recommends 1–2 grams of the whole herb per day.<sup>5</sup> Intake of tincture should be limited to 1–2 ml three times a day. Bugleweed is often combined with other herbs used to treat mildly overactive thyroid function, including **lemon balm** (page 701) (*Melissa officinalis*) and gromwell (*Lithospermum ruderale*).

### Are there any side effects or interactions?

Excessive intake of bugleweed by people with thyroid disease or use by healthy people may cause a potentially

harmful decrease in thyroid function. Thyroid disease is dangerous and should only be treated under the supervision of a healthcare professional. However, long-term use of bugleweed is considered safe for people with hyperthyroidism.<sup>6</sup> Bugleweed should not be taken by people with **hypothyroidism** (page 252). Bugleweed should also not be used during **pregnancy** (page 363) and breast-feeding.<sup>7</sup>

## BUPLEURUM

**Common names:** Thorowax, saiko, hare's ear, chai hu

**Botanical names:** *Bupleurum chinense*, *Bupleurum falcatum*

### Parts used and where grown

These Asian plants are part of the *Apiaceae (Umbelliferae)* family, and resemble dill or fennel. However, bupleurum has long thin leaves rather than the lacy appearance of fennel and dill leaves. The Chinese name for bupleurum, *chai hu*, means "kindling of the barbarians." The origin of this name is unclear. The roots of the plant are used in herbal medicine.

**Bupleurum has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Epilepsy</b> (page 183) <b>Hepatitis</b> (page 220) (viral) <b>Irritable bowel syndrome</b> (page 280) (Chinese herbal combination formula containing <b>wormwood</b> [page 762], <b>ginger</b> [page 680], <b>bupleurum</b> , <b>schisandra</b> [page 744], <b>dan shen</b> , and other extracts) <b>Liver cirrhosis</b> (page 290)
★☆☆	<b>HIV/AIDS</b> (page 239)

### Historical or traditional use (may or may not be supported by scientific studies)

Bupleurum has been used in Traditional Chinese Medicine for thousands of years to help relieve numerous conditions. Most particularly, **infections** (page 265) with fever, liver problems, **indigestion** (page 260), **hemorrhoids** (page 219), and uterine prolapse.<sup>1</sup>

Bupleurum is a key ingredient in the formula known as sho-saiko-to. This is a Japanese kampo or traditional herbal medicine formula based on the traditional Chi-

nese formula xiao-chai-hu-tang. In English, it has been called minor bupleurum formula. Bupleurum makes up 16% of the formula for sho-saiko-to (see below for the complete contents of the formula). Results reported for sho-saiko-to cannot be attributed solely to bupleurum because the other herbs in the formula also contribute.<sup>2</sup>

Sho-saiko-to (xao-chai-hu-tang or minor bupleurum formula) contains the following:

- *Bupleurum falcatum* (thorowax) root, 16%
- *Paeonia lactiflora* (peony) root, 16%
- *Pinellia ternata* (ban xia) rhizome, 14%
- *Cinnamomum cassia* (cassia) bark, 11%
- *Zingiber officinale* (page 680) (ginger) rhizome, 11%
- *Zizyphus jujuba* (jujube) fruit, 11%
- *Panax ginseng* (page 630) (Asian ginseng) root, 8%
- *Scutellaria baicalensis* (page 658) (Chinese scullcap) root, 8%
- *Glycyrrhiza uralensis* (page 702) (licorice, gan cao) rhizome, 5%

### Active constituents

Bupleurum contains constituents known as saikosaponins that appear to account for much of the medicinal activity of the plant. Test tube studies have shown that the sho-saiko-to combination can increase production of various chemicals (known as cytokines) that immune cells use to signal one another.<sup>3</sup> Test tube studies have also found that saikosaponins can inhibit growth of liver cancer cells,<sup>4</sup> and are anti-inflammatory.<sup>5,6</sup>

Human trials, only one double-blind, have shown that the bupleurum-containing formula sho-saiko-to may help reduce symptoms and blood liver enzyme levels in children and adults with chronic active viral **hepatitis** (page 220).<sup>7, 8, 9, 10</sup> Most of these studies were in people with hepatitis B infection, though one preliminary human trial has also shown a benefit in people with hepatitis C.<sup>11</sup> Sho-saiko-to was also found, in a large, preliminary (but not double-blind), study to decrease the risk of people with chronic viral hepatitis developing liver cancer.<sup>12</sup>

Sho-saiko-to has also been used to reduce symptoms of and possibly decrease the severity of **liver cirrhosis** (page 290), though clinical studies on this condition are generally lacking. One randomized trial (it was unclear if this trial was double-blind) found that sho-saiko-to could reduce the rate of liver cancer in people with liver cirrhosis.<sup>13</sup>

Several uncontrolled trials in Japan have shown that

sho-saiko-to or very similar traditional Japanese and Chinese herbal formulas (all containing bupleurum) can reduce seizure frequency and/or severity in people with **epilepsy** (page 183) that does not respond to anti-seizure medications.<sup>14, 15, 16, 17</sup> However, double-blind trials are still needed to determine the importance of these findings.

Sho-saiko-to has been found to inhibit human immunodeficiency virus (**HIV** [page 239]) in the test tube.<sup>18</sup> Yet, it is unclear to what degree bupleurum or saikosaponins contributed to this effect. Sho-saiko-to also increased the efficacy of the standard anti-HIV drug lamivudine in the test tube.<sup>19</sup> Human data are lacking on the benefit of sho-saiko-to or bupleurum in people with HIV infection or acquired immunodeficiency syndrome (AIDS).

### How much is usually taken?

Generally 500–2,000 mg bupleurum dry root are taken three times daily in capsules.<sup>20</sup> Traditionally, and in some clinical studies, bupleurum was prepared as a tea in which the root is decocted or cooked for hours before use. Some people take 1–4 grams per cup of water, three times daily. Sho-saiko-to formula is typically given in capsules (1.8–2.5 grams) three times per day. The amount given to children should be proportionally reduced based on individual weight and height as compared to adults.<sup>21</sup>

### Are there any side effects or interactions?

Bupleurum and sho-saiko-to taken as a tea can upset the stomach, an effect that tends to be lessened by taking them with food or in capsules. Bupleurum and sho-saiko-to are not recommended during **pregnancy** (page 363) and breast-feeding.

Sho-saiko-to has been used alone and with interferon to treat **hepatitis** (page 220). Eighty or more cases of drug-induced pneumonitis (inflammation of the lungs) have been associated with the use of sho-saiko-to alone or with interferon.<sup>22, 23, 24, 25, 26</sup> Until more is known, sho-saiko-to should not be combined with interferon.

## BURDOCK

**Botanical name:** *Arctium lappa*

### Parts used and where grown

Burdock is native to Asia and Europe. The root is the primary source of many herbal preparations. The root

becomes very soft with chewing and tastes sweet, with a mucilaginous (sticky) texture.

**Burdock has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Acne rosacea</b> (page 4)
	<b>Acne vulgaris</b> (page 6)
	<b>Menopause</b> (page 311)
	<b>Psoriasis</b> (page 379)
	<b>Rheumatoid arthritis</b> (page 387)

**Historical or traditional use (may or may not be supported by scientific studies)**

In traditional herbal texts, burdock root is described as a “blood purifier” or “alterative”<sup>1</sup> and was believed to clear the bloodstream of toxins. It was used both internally and externally for **eczema** (page 177) and **psoriasis** (page 379), as well as to treat painful joints and as a diuretic. In Traditional Chinese Medicine, burdock root in combination with other herbs is used to treat **sore throats** (page 129), tonsillitis, **colds** (page 129), and even **measles** (page 307).<sup>2</sup> In Japan, it is eaten as a vegetable.

Burdock root has recently become popular as part of a tea to treat **cancer** (page 87). To date, however, research is insufficient to promote burdock for this application.<sup>3</sup>

**Active constituents**

Burdock root contains high amounts of inulin and mucilage. This may explain its soothing effects on the gastrointestinal tract. Bitter constituents in the root may also explain the traditional use of burdock to improve digestion. Additionally, burdock has been shown to reduce liver damage in animal studies.<sup>4</sup> This has not been confirmed in human studies, however. It also contains polyacetylenes that have demonstrated anti-microbial activity.<sup>5</sup> Even though test tube and animal studies have indicated some anti-tumor activity in burdock root, these results have not been duplicated in human studies.<sup>6</sup> Several animal and test tube studies have also suggested an anti-inflammatory effect of unknown compounds in burdock root or seeds, including an ability to inhibit the potent inflammation-causing chemical platelet activating factor.<sup>7,8</sup>

**How much is usually taken?**

Traditional herbalists recommend 2–4 ml of burdock root tincture per day.<sup>9</sup> For the dried root preparation in capsule form, some herbalists recommend 1–2 grams three times per day. Many herbal preparations combine burdock root with other alterative “blood cleansing” herbs, such as **yellow dock** (page 763), **red clover** (page 735), or **cleavers** (page 660).

**Are there any side effects or interactions?**

Burdock root contains approximately 50% inulin,<sup>10</sup> a fiber widely distributed in fruits, vegetables and plants. Inulin is classified as a food ingredient (not as an additive) and is considered to be safe to eat.<sup>11</sup> In fact, inulin is a significant part of the daily diet of most of the world’s population.<sup>12</sup> However, there is a report of a 39-year-old man having a life-threatening allergic reaction after consuming high amounts of inulin from multiple sources.<sup>13</sup> Allergy to inulin in this individual was confirmed by laboratory tests. Such sensitivities are exceedingly rare. Moreover, this man did not take burdock. Nevertheless, people with a confirmed sensitivity to inulin should avoid burdock. There is one published case report of a severe allergic reaction, apparently due to burdock itself.<sup>14</sup>

## BUTCHER'S BROOM

**Botanical name:** *Ruscus aculeatus*

**Parts used and where grown**

Butcher’s broom is a spiny, small-leaved evergreen bush native to the Mediterranean region and northwest Europe. It is a member of the lily family and is similar, in many ways, to asparagus. The roots and young stems of butcher’s broom are used medicinally.

**Butcher's broom has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Chronic venous insufficiency</b> (page 116)
★☆☆	<b>Atherosclerosis</b> (page 38) <b>Varicose veins</b> (page 440)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Butcher's broom is so named because the mature branches were bundled and used as brooms by butchers. The young shoots were sometimes eaten as food. Ancient physicians used the roots as a diuretic in the treatment of urinary problems.<sup>1</sup>

#### **Active constituents**

Steroidal saponins are thought to be responsible for the medicinal actions of butcher's broom.<sup>2</sup> These constituents are reported to improve the strength and tone of the veins and act as mild diuretics. They may also lead to constriction of the veins, which helps blood return from the extremities.<sup>3, 4</sup> Butcher's broom extracts also exert a mild anti-inflammatory effect.

Clinical trials, one double-blind, have confirmed the benefit of a combination of **vitamin C** (page 604), **flavonoids** (page 516), and butcher's broom for treatment of **chronic venous insufficiency** (page 116) (CVI).<sup>5, 6</sup> In a comparison study, a product combining butcher's broom extract, the flavonoid hesperidin, and vitamin C was more effective than a synthetic flavonoid product for treating CVI.<sup>7</sup> A double-blind study, in which Butcher's broom alone was used, has confirmed the beneficial effect of this herb in the treatment of CVI.<sup>8</sup>

#### **How much is usually taken?**

Encapsulated butcher's broom extracts, in the amount of 1,000 mg three times per day, can be used for **chronic venous insufficiency** (page 116). These extracts are often combined with vitamin C and/or flavonoids. Standardized extracts (9–11% ruscogenins) can be taken in the amount of 100 mg three times per day.

#### **Are there any side effects or interactions?**

Side effects are rarely seen if butcher's broom is used as directed above. However, in certain cases, butcher's broom can cause nausea.<sup>9</sup>

## **CALENDULA**

**Common name:** Marigold

**Botanical name:** *Calendula officinalis*

#### **Parts used and where grown**

Calendula grows as a common garden plant throughout North America and Europe. The golden-orange or yel-

low flowers of calendula have been used as medicine for centuries.

### **Calendula has been used in connection with the following conditions (refer to the individual health concern for complete information):**

Rating	Health Concerns
★☆☆	<b>Dermatitis</b> (page 151) (radiation-induced)
★☆☆	<b>Breast-feeding support</b> (page 74) (topical for sore nipples)
	<b>Burns (minor, including sunburn)</b> (page 85)
	<b>Conjunctivitis/blepharitis</b> (page 136)
	<b>Eczema</b> (page 117)
	<b>Peptic ulcer</b> (page 349)
	<b>Ulcerative colitis</b> (page 433)
	<b>Wound healing</b> (page 319) (topical)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Calendula flowers were historically considered beneficial for reducing inflammation, **wound healing** (page 319), and as an antiseptic. Calendula was used to treat various skin diseases, ranging from skin ulcerations to **eczema** (page 117).<sup>1</sup> Internally, the soothing effects of calendula have been used for **stomach ulcers** (page 349) and inflammation. Traditionally, a sterile tea was topically applied in cases of **conjunctivitis** (page 136).

#### **Active constituents**

**Flavonoids** (page 516), found in high amounts in calendula, are thought to account for much of its anti-inflammatory activity.<sup>2</sup> Other potentially important constituents include the triterpene saponins<sup>3</sup> and **carotenoids** (page 488).

Investigations into anticancer and antiviral actions of calendula are continuing. At this time, insufficient evidence exists to recommend the use of calendula for **cancer** (page 87). Nevertheless, test tube studies have found antiviral activity for calendula.<sup>4, 5</sup> The constituents responsible for these actions are not clear, however, and the relevance of these actions for human health care has not been established.

#### **How much is usually taken?**

A tea of calendula can be made by pouring 1 cup (250 ml) of boiling water over 1–2 teaspoons (5–10 grams) of the flowers; the tea is then steeped, covered for ten to fifteen minutes, strained, and drunk.<sup>6</sup> At least 3 cups of tea are recommended per day. Tincture is similarly used

three times a day, at  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–2 ml) each time. The tincture can be taken in water or tea. In addition, prepared ointments can be used topically for skin problems, although wet dressings made by dipping a cloth into the cooled tea are also effective. Topical treatment for eye conditions is not recommended, as absolute sterility must be maintained.

#### **Are there any side effects or interactions?**

Side effects are rare with the use of calendula. Some people may experience a skin rash with topical use and should be tested to see if they are allergic to the herb.

## CARAWAY

**Botanical name:** *Carum carvi*

#### **Parts used and where grown**

Caraway is a biennial that is widely cultivated throughout the world, and is native to Europe, Asia, and North Africa. The dried ripe fruit or seeds are used medicinally.<sup>1</sup>

**Caraway has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Irritable bowel syndrome</b> (page 280) (combination with <b>peppermint</b> (page 726) oil)
★★☆	<b>Gingivitis</b> (page 203) (periodontal disease) (as mouthwash, in combination with <b>sage</b> [page 740], <b>peppermint</b> [page 726] oil, menthol, <b>chamomile</b> [page 656] tincture, expressed juice from <b>echinacea</b> [page 669], <b>myrrh</b> [page 713] tincture, and clove oil) <b>Indigestion</b> (page 260)
★☆☆	<b>Colic</b> (page 121)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

The use of caraway as a medicinal agent has remained unchanged for centuries. Its use as a digestive aid was first mentioned in the Egyptian *Eberus Papyrus* about 1500 B.C.<sup>2</sup> In Shakespeare's *Henry IV*, the character Falstaff is invited to have a serving of baked apples and caraway to aid the digestion and relieve gas.<sup>3</sup> Nine-

teenth-century American Eclectic physicians (doctors who recommended herbs), such as Harvey Felter, pointed out the seeds not only promote digestion but also ease the symptoms of children suffering from digestive **colic** (page 121).<sup>4</sup>

#### **Active constituents**

Caraway contains 3–7% volatile oil, with the main components divided into carvone (50–60%) and limonene (40%).<sup>5</sup> The fruit also contains approximately 10% fixed oil along with 20% carbohydrate and 20% protein. Caraway belongs to a class of herbs called carminatives, which are plants helpful in easing gastrointestinal discomfort, including gas. The volatile oils derived from this group of plants may help alleviate bowel spasm.<sup>6</sup>

There are no human clinical trials on caraway as a single entity. However, it has been used with success in combination with enteric-coated **peppermint oil** (page 726) in the treatment of **irritable bowel syndrome** (page 280) (IBS).<sup>7,8</sup> People using this combination reported experiencing less pain and noted an overall improvement in their bowel symptoms compared to those who took a comparable placebo. A combination of caraway with the other carminative herbs anise and **fennel** (page 676) has shown to be helpful in dealing with conditions of flatulence and mild abdominal cramping, especially in children.<sup>9</sup>

#### **How much is usually taken?**

Use approximately  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (0.5–2 grams) of powdered caraway fruit to make tea; drink it three times a day. Tinctures of the extracted herb (0.5–4 ml) are sometimes used three times per day. The enteric-coated volatile oil (0.05–0.2 ml) can be taken three times daily (usually in combination with enteric-coated **peppermint** (page 726) oil) for **irritable bowel syndrome** (page 280).<sup>10</sup>

#### **Are there any side effects or interactions?**

Caraway is generally safe for internal use. However, the purified volatile oil should not be used by children under two years of age, as oil from caraway and other herbs in the *Umbelliferae* family can be irritating to the skin and mucous membranes.<sup>11</sup> Large amounts of the oil (several times higher than the dosages listed above) may be potentially abortifacient and neurotoxic and should be avoided, especially by **pregnant** (page 363) women.

## CAROB

**Common names:** St. John's bread, locust bean  
**Botanical name:** *Ceratonia siliqua*

### Parts used and where grown

Carob is originally from the Mediterranean region and the western part of Asia. Today it is grown mostly in Mediterranean countries. The gum from carob seeds is called locust bean gum. The dried, powdered pods of the plant are used in herbal medicine.

**Carob has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Diarrhea (page 163)

### Historical or traditional use (may or may not be supported by scientific studies)

Carob has long been eaten as food. John the Baptist is said to have eaten it, and thus it is sometimes called St. John's bread. Powdered carob pods have been used to treat **diarrhea** (page 163) for centuries.

### Active constituents

The main constituents of carob are sugars and tannins. Carob tannins have an astringent effect in the gastrointestinal tract making them useful for treating **diarrhea** (page 163). They may also bind to (and thereby inactivate) toxins and inhibit growth of bacteria. The sugars make carob gummy and able to act as a thickener to absorb water—another action that may help decrease diarrhea. A double-blind clinical trial found carob useful for treating diarrhea in infants.<sup>1</sup> A less rigorous trial showed it did not help adults with traveler's diarrhea.<sup>2</sup>

### How much is usually taken?

Some trials have used up to 15 grams of carob powder for treating **diarrhea** (page 163) in children.<sup>3</sup> Adults should take at least 20 grams a day for treating diarrhea. The powder can be mixed in applesauce or with sweet potatoes. Carob should be taken with plenty of water. Please note that infant diarrhea must be monitored by a healthcare professional and that proper hydration with a high electrolyte fluid is critical during acute diarrhea.

### Are there any side effects or interactions?

Carob is generally safe. Only rarely have allergic reactions been reported.

## CASCARA

**Common names:** Cascara sagrada, sacred bark  
**Botanical names:** *Cascara sagrada, Rhamnus purshiana* cortex

### Parts used and where grown

Cascara is a small to medium-size tree native to the provinces and states of the Pacific coast, including British Columbia, Washington, Oregon, and northern California. The bark of the tree is removed, cut into small pieces, and dried for one year before being used medicinally. Fresh cascara bark has an emetic or vomit-inducing property and therefore is not used.

**Cascara has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Constipation (page 137)

### Historical or traditional use (may or may not be supported by scientific studies)

Northern California Indians introduced this herb, which they called sacred bark, to 16th century Spanish explorers. As it is much milder in its laxative action than the herb buckthorn, cascara became popular in Europe as a treatment for **constipation** (page 137). Cascara has been an approved treatment for constipation in the U.S. Pharmacopoeia since 1890.<sup>1</sup>

### Active constituents

Cascara bark is high in hydroxyanthraquinone glycosides called cascarosides. Resins, tannins, and lipids make up the bulk of the other bark ingredients. Cascarosides have a cathartic action that induces the large intestine to increase its muscular contraction (peristalsis), resulting in bowel movement.<sup>2</sup>

### How much is usually taken?

Only the dried form of cascara should be used. Capsules providing 20–30 mg of cascarosides per day can

be used. However, the smallest amount necessary to maintain soft stool should be used.<sup>3</sup> As a tincture,  $\frac{1}{4}$ –1 teaspoon (1–5 ml) per day is generally taken. It is important to drink eight 6-ounce (180 ml) glasses of water throughout the day while using cascara. Cascara should be taken consecutively for no longer than eight to ten days.<sup>4</sup>

#### **Are there any side effects or interactions?**

Women who are **pregnant** (page 363) or breast-feeding, and children under the age of 12 should not use cascara without the advice of a physician. People with an intestinal obstruction, **Crohn's disease** (page 141), appendicitis or abdominal pain should not employ this herb.<sup>5</sup> Long-term use or abuse of cascara may result in weakened bowel function. It may also cause a loss of electrolytes (especially the mineral **potassium** [page 572]). Loss of potassium can lead to abnormalities of heart function and may augment the action of digitalis-like medications with fatal consequences.

## **CATNIP**

**Botanical name:** *Nepeta cataria*

#### **Parts used and where grown**

Catnip is a whitish-gray plant with a minty odor. The flowers are white with crimson dots. The catnip plant grows in North America and Europe. The leaves and flowers are used as medicine.

**Catnip has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Cough</b> (page 139) <b>Insomnia</b> (page 270)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Catnip is famous for inducing a delirious, stimulated state in felines. Throughout history, this herb has been used in humans to produce a sedative effect.<sup>1</sup> Several other conditions (including **cancer** [page 87], toothache, corns, and **hives** [page 245]) have been treated with catnip by traditional herbalists.

#### **Active constituents**

The volatile oil in catnip contains the monoterpane, nepetalactone, which is similar to the valepotriates found in **valerian** (page 756), a more commonly used herbal sedative.<sup>2</sup> Human trials are lacking to prove the effectiveness of catnip for treating **insomnia** (page 270). It has been used traditionally to reduce gas and act as a digestive aid.<sup>3</sup>

#### **How much is usually taken?**

A catnip tea can be made by adding 1 cup (250 ml) of boiling water to 1–2 teaspoons (5–10 grams) of the herb; cover, then steep for ten to fifteen minutes. Drink 2–3 cups per day.<sup>4</sup> For children with **coughs** (page 139), 1 teaspoon (5 ml) of tincture three times per day can be used. Adults may take twice this amount.

#### **Are there any side effects or interactions?**

No common side effects have been associated with the use of catnip. Since catnip (particularly the volatile oil) may act to promote uterine contractions, it should not be used during **pregnancy** (page 363).

## **CAT'S CLAW**

**Common name:** Uña de gato

**Botanical name:** *Uncaria tomentosa*

#### **Parts used and where grown**

Cat's claw grows in the rain forests of the Andes Mountains in South America, particularly in Peru. The two species of the plant used most commonly are *U. tomentosa*, which makes up most of the cat's claw imported to the U.S., and *U. guianensis*, which is more widely used in Europe. In South America, both species are used interchangeably. The root bark is used as medicine.

**Cat's claw has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Osteoarthritis</b> (page 328)
★☆☆	<b>HIV support</b> (page 239) <b>Immune function</b> (page 255) <b>Rheumatoid arthritis</b> (page 387)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Cat's claw has been reportedly used by indigenous peoples in the Andes to treat inflammation, rheumatism, gastric ulcers, tumors, dysentery, and as birth control.<sup>1</sup> Cat's claw is popular in South American folk medicine for treating intestinal complaints, gastric ulcers, arthritis, and to promote **wound healing** (page 319).

### **Active constituents**

According to test tube studies, oxyindole alkaloids in cat's claw stimulate **immune function** (page 255).<sup>2</sup> Alkaloids and glycosides in cat's claw have also demonstrated anti-inflammatory and antioxidant activity.<sup>3,4</sup>

Although clinical trials are lacking, cat's claw has become very popular in North America and is sometimes recommended for people with **cancer** (page 87) or **HIV** (page 239) infection. A cigarette smoker who took a freeze-dried extract of cat's claw root bark for one month showed a sharp decrease in one urinary cancer marker.<sup>5</sup> This finding, however, does little to support the use of the herb in persons with cancer and points toward the need for actual clinical studies to determine its effectiveness.

Cat's claw has been used traditionally for **osteoarthritis** (page 328) and **rheumatoid arthritis** (page 387). In a double-blind trial, 100 mg per day of a freeze-dried preparation of cat's claw taken for four weeks was significantly more effective than a placebo at relieving pain and improving the overall condition.<sup>6</sup>

### **How much is usually taken?**

In a study of patients with **osteoarthritis** (page 328), 100 mg per day of a freeze-dried preparation was used. Cat's claw tea is prepared from  $\frac{1}{4}$  teaspoon (1 gram) of root bark by adding 1 cup (250 ml) of water and boiling for ten to fifteen minutes. Cool, strain and drink one cup three times per day. Alternatively,  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–2 ml) of tincture can be taken up to two times per day, or 20–60 mg of a dry standardized extract can be taken once per day.<sup>7</sup>

### **Are there any side effects or interactions?**

Although no serious adverse effects have been reported for cat's claw, there is little known about its safety because most reports have been based on anecdotal evidence. Cat's claw should be used with caution in people with autoimmune illness, **multiple sclerosis** (page 323), and tuberculosis. Until proven safe, cat's claw should not be taken by **pregnant** (page 363) or **breast-feeding** (page 74) women.

## **CAYENNE**

**Botanical names:** *Capsicum annuum*, *Capsicum frutescens*

### **Parts used and where grown**

Originally from South America, the cayenne plant is now used worldwide as a food and spice. Cayenne is very closely related to bell peppers, jalapeños, paprika, and other similar peppers. The fruit is used medicinally.

**Cayenne has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Diabetes</b> (page 152) (topical for neuropathy) Neurogenic bladder (administered by urologist) <b>Osteoarthritis</b> (page 328) (topical, for pain only) <b>Pain</b> (page 338) (topical use only) <b>Psoriasis</b> (page 379) (topical) <b>Shingles (herpes zoster)/postherpetic neuralgia</b> (page 401) (topical, for pain only)
★★☆	<b>Cluster headaches</b> (page 117) <b>Indigestion and heartburn</b> (page 260) Itching (anal; pruritus ani) <b>Obesity</b> (page 446) <b>Rheumatoid arthritis</b> (page 387) (topical)
★☆☆	<b>Bursitis</b> (page 87) <b>Low back pain</b> (page 293) (topical) <b>Migraine headaches</b> (page 316)

### **Historical or traditional use (may or may not be supported by scientific studies)**

The potent, hot fruit of cayenne has been used as medicine for centuries. It was considered helpful by herbalists for various conditions of the gastrointestinal tract, including stomach aches, cramping pains, and gas. Cayenne was frequently used to treat diseases of the circulatory system. It is still traditionally used in herbal medicine as a circulatory tonic (a substance believed to improve circulation). Rubbed on the skin, cayenne is a traditional, as well as modern, remedy for rheumatic pains and arthritis due to what is termed a counterirritant effect. A counterirritant is something that causes irritation to a tissue to which it is applied, thus distracting from the original irritation (such as joint pain in the case of arthritis).

### **Active constituents**

Cayenne contains a resinous and pungent substance known as capsaicin. Topical application of capsaicin re-

lieves pain and itching by acting on sensory nerves.<sup>1</sup> Capsaicin temporarily depletes “substance P”, a chemical in nerves that transmits pain sensations. Without substance P, pain signals can no longer be sent. The effect is temporary. Numerous double-blind trials have proven topically applied capsaicin creams are helpful for a range of conditions, including nerve pain in **diabetes** (page 152) (diabetic neuropathy),<sup>2,3</sup> post-surgical pain,<sup>4,5,6</sup> **psoriasis** (page 379),<sup>7</sup> muscle pain due to **fibromyalgia** (page 191),<sup>8</sup> nerve pain after **shingles** (page 401) (postherpetic neuralgia),<sup>9,10</sup> **osteoarthritis** (page 328) pain,<sup>11,12</sup> and **rheumatoid arthritis** (page 387) pain.<sup>13</sup>

With the aid of a healthcare professional, capsaicin administered via the nose may also be a potentially useful therapy for **cluster headaches** (page 117). This is supported by a double-blind trial.<sup>14</sup> Weaker scientific support exists for the use of capsaicin for **migraines** (page 316).<sup>15</sup>

Injecting capsaicin directly into the urinary bladder has reduced symptoms of one type of bladder dysfunction (neurogenic hyperreflexic bladder)<sup>16</sup> that results from spinal cord and other nerve injuries. Capsaicin is not known to help other bladder conditions, such as chronic bladder pain. The placing of cayenne or capsaicin products into the bladder has only been performed in clinical experiments and should only be done by a urologist.

Modest reductions in appetite have been found in healthy Japanese women and white men when they consumed 10 grams of cayenne pepper along with meals in a double-blind trial.<sup>17</sup> A similar trial found that cayenne could increase metabolism of dietary fats in Japanese women.<sup>18</sup> These trials suggest cayenne may help in the treatment of **obesity** (page 446).

In a double-blind study of people with dyspepsia (**heartburn** [page 260]), supplementation with 833 mg of cayenne powder in capsules, three times per day before meals, reduced heartburn symptoms by 48%, compared with a placebo. However, two of 15 individuals receiving cayenne discontinued it because of abdominal pain.<sup>19</sup>

#### How much is usually taken?

Topical creams containing 0.025% to 75% capsaicin are generally used.<sup>20</sup> People often apply the cream to the affected area three or four times per day. A burning sensation may occur the first several times the cream is applied. However, this should gradually decrease with each use. The hands must be carefully and thoroughly

washed after use, or gloves should be worn, to prevent the cream from accidentally reaching the eyes, nose, or mouth, which would cause a burning sensation. Do not apply the cream to areas of broken skin. For internal use, cayenne tincture (0.3–1 ml) can be taken three times per day. An infusion can be made by pouring 1 cup (250 ml) of boiling water onto  $\frac{1}{2}$ –1 teaspoon (2.5 to 5 grams) of cayenne powder and let set for 10 minutes. A teaspoon of this infusion can be mixed with water and taken three to four times daily. In the treatment of heartburn, researchers have used 833 mg of cayenne powder in capsule form, taken three times per day before meals.<sup>21</sup>

#### Are there any side effects or interactions?

Besides causing a mild burning during the first few applications (or severe burning if accidentally placed in sensitive areas, such as the eyes), side effects are few with the use of capsaicin cream.<sup>22</sup> As with anything applied to the skin, some people may have an allergic reaction to the cream, so the first application should be to a very small area of skin. Do not attempt to use capsaicin cream intra-nasally for headache treatment without professional guidance.

When consumed as food—one pepper per day for many years—cayenne may increase the risk of stomach cancer, according to one study.<sup>23</sup> A different human study found that people who ate the most cayenne actually had lower rates of stomach cancer.<sup>24</sup> Overall, the current scientific evidence is contradictory. Thus, the relationship between cayenne consumption and increased risk of stomach cancer remains unclear.<sup>25</sup> Oral intake of even 1 ml of tincture three times per day can cause burning in the mouth and throat, and can cause the nose to run and eyes to water. People with **ulcers** (page 349), **heartburn** (page 260), or **gastritis** (page 195) should use any cayenne-containing product cautiously as it may worsen their condition.

## CENTAURY

**Botanical name:** *Centaurium minus*

#### Parts used and where grown

This small grassland plant is native to Eurasia. The leaves, stems, and flowers of centaury are used medicinally.

**Centaury has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Hypochlorhydria</b> (page 260) (low stomach acid) <b>Indigestion</b> (page 260) Loss of appetite

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Centaury is one of the mainstays of European folk herbalism as a tonic for the digestive tract.<sup>1</sup> It was also used as a general tonic for people who had fevers.

#### **Active constituents**

Centaury contains bitter glycosides that stimulate secretion of stomach acid and digestive enzymes as well as activity of the entire digestive tract.<sup>2</sup> Centaury is recommended by the German Commission E for people with poor appetite and **indigestion** (page 260).<sup>3</sup> One preliminary animal study showed the herb had anti-inflammatory and fever-lowering effects.<sup>4</sup>

#### **How much is usually taken?**

Centaury is generally taken prior to a meal. A tea is made by adding 1 to 2 teaspoons of the herb to one cup of hot water and allowing it to steep for 15 minutes.<sup>5</sup> The tea should be sipped slowly. The bitter taste can be covered up by adding **ginger** (page 680) tea. Alternatively, capsules can be used in the amount of 1 to 2 grams three times per day before a meal.<sup>6</sup>

#### **Are there any side effects or interactions?**

Centaury could theoretically worsen the conditions of **peptic ulcer disease** (page 349), elevated stomach acid levels, **heartburn** (page 260), **gastroesophageal reflux disease** (page 198), **diarrhea** (page 152), or acute inflammation of the intestinal tract, such as **Crohn's disease** (page 141), and should be avoided in such cases. Centaury is otherwise safe.<sup>7</sup> The safety of centaury in **pregnancy** (page 363) and **breast-feeding** (page 74) is unknown.

## CHAMOMILE

**Botanical name:** *Matricaria recutita*

#### **Parts used and where grown**

Chamomile, a member of the daisy family, is native to Europe and western Asia. German chamomile is the most commonly used. The dried and fresh flowers are used medicinally.

#### **Chamomile has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Colic</b> (page 121) <b>Eczema</b> (page 177) <b>Gingivitis</b> (page 203) (periodontal disease) (as mouthwash, in combination with <b>sage</b> [page 740], <b>peppermint</b> [page 726] oil, menthol, expressed juice from <b>echinacea</b> [page 669], <b>myrrh</b> [page 713] tincture, and <b>caraway</b> [page 651] oil) <b>Wound healing</b> (page 319)
★☆☆	<b>Anxiety</b> (page 30) <b>Canker sores</b> (page 90) <b>Conjunctivitis/blepharitis</b> (page 136) <b>Crohn's disease</b> (page 141) <b>Diarrhea</b> (page 163) <b>Gastritis</b> (page 195) <b>Gingivitis</b> (page 203) (periodontal disease) <b>Indigestion and heartburn</b> (page 260) <b>Insomnia</b> (page 270) <b>Irritable bowel syndrome</b> (page 280) <b>Peptic ulcer</b> (page 349) <b>Ulcerative colitis</b> (page 433)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Chamomile has been used for centuries in Europe as a medicinal plant, mostly for gastrointestinal complaints. This practice continues today.

#### **Active constituents**

The flowers of chamomile contain 1–2% volatile oils including alpha-bisabolol, alpha-bisabolol oxides A & B, and matricin (usually converted to chamazulene).<sup>1</sup> Other active constituents include the **flavonoids** (page 516) apigenin, luteolin, and **quercetin** (page 580). These active ingredients contribute to chamomile's

anti-inflammatory, antispasmodic, and smooth-muscle relaxing action, particularly in the gastrointestinal tract.<sup>2, 3, 4, 5</sup>

Topical applications of chamomile have been shown to be moderately effective in the treatment of **eczema** (page 177).<sup>6, 7</sup> One double-blind trial found it to be about 60% as effective as 0.25% hydrocortisone cream.<sup>8</sup> Topical use of chamomile ointment was also found to successfully treat mild stasis ulcers bed sores in elderly bedridden patients.<sup>9</sup>

### How much is usually taken?

Chamomile is often taken three to four times daily between meals<sup>10</sup> as a tea. Common alternatives are to use 2–3 grams of the herb in tablet or capsule form or 4–6 ml of tincture three times per day between meals. Standardized extracts containing 1% apigenin and 0.5% volatile oils may also be used. One to two capsules containing 300–400 mg of extract may be taken three times daily. Topical creams or ointments can be applied to the affected area three to four times daily.

### Are there any side effects or interactions?

Though rare, allergic reactions to chamomile have been reported.<sup>11</sup> These reactions have included bronchial constriction with internal use and allergic skin reactions with topical use.<sup>12</sup> While reports of such side effects are uncommon, people with allergies to plants of the Asteraceae family (ragweed, aster, and chrysanthemums), as well as mugwort pollen should avoid using chamomile.<sup>13</sup> Chamomile is usually considered to be safe during **pregnancy** (page 363) or breast-feeding. However, there is one case report in which a pregnant woman who took chamomile as an enema had an allergic reaction that led to the death of her newborn.<sup>14</sup>

## CHAPARRAL

**Common names:** Creosote bush, greasewood

**Botanical name:** *Larrea tridentata*

### Parts used and where grown

Chaparral takes its name from the area in which it grows, the desert regions of the southwestern United States and northern Mexico known as the chaparral ecosystem. The leaves and stems of this ancient plant are used as medicine.

**Chaparral has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Cold sores</b> (page 119) <b>Indigestion and heartburn</b> (page 260) <b>Infection</b> (page 265) <b>Intestinal cramps (topical)</b> <b>Parasites</b> (page 343) <b>Rheumatoid arthritis</b> (page 387) (topical) <b>Wound healing</b> (page 319) (topical)

### Historical or traditional use (may or may not be supported by scientific studies)

Chaparral has been used for thousands of years by Native Americans for a variety of purposes. It has been employed primarily in tea form to help with cramping pains, joint pains, and allergic problems, as well as to eliminate **parasites** (page 343).<sup>1, 2</sup> Externally it has been applied to reduce inflammation and pain, and to promote healing of **minor wounds** (page 319).<sup>3</sup>

### Active constituents

The major lignan in chaparral, known as nordihydroguaiaretic acid (NDGA) is a potent antioxidant and was thought by some scientists to be a potential cancer treatment. In a rat study, NDGA and a leaf extract of a South American subspecies of chaparral were found to exert an antitumor effect.<sup>4</sup> However, one report suggests that NDGA may stimulate further growth of tumors in cancer patients.<sup>5</sup> Clinical trials, therefore, are still needed to establish whether chaparral is a safe and effective treatment for people with cancer.

Other reported effects for chaparral include anti-inflammatory properties<sup>6, 7</sup> as well as antimicrobial actions in test tubes.<sup>8</sup> These actions have not been established in human clinical trials.

### How much is usually taken?

A tea can be prepared by steeping 1 teaspoon (approximately 5 grams) of leaves and flowers in 1 cup (250 ml) of hot water for ten to fifteen minutes.<sup>9</sup> People should drink three cups per day for a maximum of two weeks unless under the care of a physician expert in the use of botanical medicines. Alternatively, 0.5–1 ml of tincture can be taken three times per day.<sup>10</sup> Topically, cloths can be soaked in oil preparations or tea of chaparral and applied several times per day (with heat if helpful) over

the affected area. Capsules of chaparral should be avoided.

#### **Are there any side effects or interactions?**

There have been sporadic reports of people developing liver or kidney problems after taking chaparral, particularly in capsules.<sup>11</sup> Almost all of these cases involved either the use of capsules or excessive amounts of tea. Some of these cases were people with established liver disease prior to using the herb. Tea and tincture of chaparral have an extremely strong taste considered disagreeable by most people, which restricts the amount they can tolerate before feeling nauseous. Capsules bypass this protective mechanism and should therefore be avoided. Since human studies have shown that large amounts of chaparral tea and injections of NDGA in people with **cancer** (page 87) do not cause liver or kidney problems,<sup>12</sup> it is likely the cases of toxicity represented individual reactions.<sup>13</sup>

#### **Special United Kingdom considerations**

Chaparral is either not available or may require a prescription. People should check with a qualified herbalist.

## **CHICKWEED**

**Botanical name:** *Stellaria media*

#### **Parts used and where grown**

The small, green chickweed plant originated in Europe, but now grows across the United States. The leaves, stems, and flowers are used medicinally.

**Chickweed has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Eczema</b> (page 177) Insect stings and bites

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Chickweed was reportedly used at times for food.<sup>1</sup> It enjoys a reputation in folk medicine for treating a wide spectrum of conditions, ranging from **asthma** (page 32) and **indigestion** (page 260) to skin diseases such as **eczema** (page 177) and **psoriasis** (page 379). It is

sometimes used to alleviate itching secondary to insect bites.

#### **Active constituents**

The active constituents in chickweed are largely unknown. It contains relatively high amounts of vitamins (e.g., **vitamin C** [page 604]) and **flavonoids** (page 516), which may partly explain its effectiveness as a topical treatment for skin irritations and itching. Although some older information suggests a possible benefit for chickweed in rheumatic conditions, this has not been validated in clinical trials.<sup>2</sup>

#### **How much is usually taken?**

Although formerly used as a tea, chickweed is mainly used today as a cream applied liberally several times each day to rashes and inflammatory skin conditions (e.g., **eczema** [page 177]) to ease itching and inflammation.<sup>3</sup> As a tincture,  $\frac{1}{4}$ –1 teaspoon (1–5 ml) per day can be taken three times per day. Two teaspoonfuls (10 grams) of the dried herb may also be drunk as a tea three times daily.

#### **Are there any side effects or interactions?**

No side effects with chickweed have been reported.

## **CHINESE SCULLCAP**

**Common name:** Baikal scullcap

**Botanical name:** *Scutellaria baicalensis*

#### **Parts used and where grown**

*Scutellaria baicalensis*, a mint family member, is grown in China and Russia. The root of this plant is used in traditional Chinese herbal medicines and has been the focus of most scientific studies on scullcap. **American scullcap** (page 626) and Chinese scullcap are not interchangeable.

**Chinese scullcap has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Epilepsy</b> (page 183) (in combination with <b>bupleurum</b> [page 647], peony root, pinellia root, cassia bark, <b>ginger</b> [page 680] root, jujube fruit, <b>Asian ginseng</b> [page 630] root, and <b>licorice</b> [page 702] root)

Rating	Health Concerns
★☆☆	<b>Bronchitis</b> (page 80) <b>Hepatitis</b> (page 220) <b>HIV support</b> (page 239) (in combination with <b>bupleurum</b> [page 647], peony root, pinellia root, cassia bark, <b>ginger</b> [page 680] root, jujube fruit, <b>Asian ginseng</b> [page 630] root, Asian scullcap root, and <b>licorice</b> [page 702] root)

#### Historical or traditional use (may or may not be supported by scientific studies)

Chinese scullcap is typically used in herbal combinations in Traditional Chinese Medicine to treat inflammatory skin conditions, **allergies** (page 14), **high cholesterol** (page 223) and **triglycerides** (page 235).<sup>1</sup>

#### Active constituents

The root of Chinese scullcap contains the **flavonoid** (page 516) baicalin that has been shown in test tube studies to have protective actions on the liver. Anti-allergy actions and the inhibition of bacteria and viruses in test tube studies have also been documented with Chinese scullcap.<sup>2</sup> Some preliminary Chinese human trials, generally of low quality, suggest that Chinese scullcap may help people with acute lung, intestinal, and liver infections, as well as **hay fever** (page 211).<sup>3</sup> More extensive clinical research is needed to clearly demonstrate Chinese scullcap's effectiveness for these conditions.

#### How much is usually taken?

In traditional Chinese herbal medicine, Chinese scullcap is typically recommended as a tea made from 3–9 grams of the dried root.<sup>4</sup> Fluid extract, 1–4 ml three times per day, is also used.<sup>5</sup>

#### Are there any side effects or interactions?

Use of Chinese scullcap in the amounts listed above appears to be safe. The safety of Chinese scullcap during **pregnancy** (page 363) and breast-feeding is unknown and should be avoided during these times.

## CINNAMON

**Botanical name:** *Cinnamomum zeylanicum*

#### Parts used and where grown

Most people are familiar with the sweet but pungent taste of the oil, powder, or sticks of bark from the cin-

namon tree. Cinnamon trees grow in a number of tropical areas, including parts of India, China, Madagascar, Brazil, and the Caribbean.

**Cinnamon has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Diabetes</b> (page 152)
★☆☆	<b>Colic</b> (page 121) <b>Indigestion and heartburn</b> (page 260) <b>Menorrhagia</b> (page 314) (heavy menstruation) Poor appetite <b>Yeast infection</b> (page 454)

#### Historical or traditional use (may or may not be supported by scientific studies)

Cinnamon is an ancient herbal medicine mentioned in Chinese texts as long ago as 4,000 years. It has a broad range of historical uses in different cultures, including the treatment of **diarrhea** (page 163), rheumatism, and certain menstrual disorders.<sup>1</sup>

#### Active constituents

Various terpenoids found in the volatile oil are believed to account for cinnamon's medicinal effects. Important among these compounds are eugenol and cinnamaldehyde. Both cinnamaldehyde and cinnamon oil vapors are potent anti-fungal compounds.<sup>2</sup> Preliminary human evidence confirms this effect in a clinical trial with **AIDS** (page 239) patients suffering from oral candida (thrush) infections that improved with topical application of cinnamon oil.<sup>3</sup> Antibacterial actions have also been demonstrated for cinnamon.<sup>4</sup> The diterpenes in the volatile oil have shown anti-allergic activity<sup>5</sup> as well. In addition, water extracts may help reduce ulcers.<sup>6</sup> Test tube studies also show that cinnamon can augment the action of insulin.<sup>7</sup> However, use of cinnamon to improve the action of insulin in people with **diabetes** (page 152) has yet to be proven in clinical trials.

#### How much is usually taken?

The German Commission E monograph suggests  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (2–4 grams) of the powder per day.<sup>8</sup> A tea can be prepared from the powdered herb by boiling  $\frac{1}{2}$  teaspoon (2–3 grams) of the powder for ten to fifteen minutes, cooling, and then drinking. No more than a few

drops of volatile oil should be used and only for a few days at a time. A tincture ( $\frac{1}{2}$  teaspoon or 2–3 ml) may also be taken three times per day.

#### **Are there any side effects or interactions?**

Some people develop bronchial constriction or skin rash after exposure to cinnamon.<sup>9</sup> Therefore, only small amounts should be used initially in people who have not previously had contact with cinnamon, and anyone with a known allergy should avoid it. Chronic use of the concentrated oil may cause inflammation in the mouth. According to the German Commission E monograph, cinnamon is not recommended for use by pregnant (page 363) women.<sup>10</sup>

## CLEAVERS

**Common names:** Bedstraw, goose grass

**Botanical name:** *Galium aparine*

#### **Parts used and where grown**

Cleavers grow in wet areas of Britain, Europe, Asia, and North America. Small prickles grow on the leaves of cleavers, causing it to have a sticky feeling and giving it its name. The leaves and flowers of cleavers are used medicinally.

**Cleavers has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Edema</b> (page 180)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Cleavers is one of numerous plants considered in ancient times to act as a diuretic.<sup>1</sup> It was therefore used to relieve **edema** (page 180) and to promote urine formation during bladder infections. It has also been used by people with lymph swellings, jaundice, and wounds.

#### **Active constituents**

Galiosin, an anthraquinone glycoside, other glycosides, tannins, and **flavonoids** (page 516) may be the major constituents of cleavers. Little research has been conducted on this plant, but preliminary lab experiments suggest it may have antispasmodic activity.<sup>2</sup>

#### **How much is usually taken?**

Cleavers tincture and tea are most widely recommended by herbal practitioners. Tincture ( $\frac{1}{2}$ –1 teaspoon or 3–5 ml) can be taken three times per day. Tea is made by steeping 2–3 teaspoons (10–15 grams) of the herb in 1 cup (250 ml) of hot water for ten to fifteen minutes. People can drink three or more cups per day.

#### **Are there any side effects or interactions?**

Cleavers has no known side effects and is thought to be safe for use by children and **pregnant** (page 363) or nursing women.

## COLEUS

**Common name:** Makandi

**Botanical name:** *Coleus forskohlii*

#### **Parts used and where grown**

This attractive, perennial member of the mint (*Lamiaceae*) family originated in the lower elevations of India. It is now grown around the world as an ornamental plant. The root is used medicinally.

**Coleus has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Asthma</b> (page 32) (forskolin) <b>Glaucoma</b> (page 205) (forskolin)
★☆☆	<b>Cardiomyopathy</b> (page 95) (forskolin) <b>Congestive heart failure</b> (page 134) <b>Hypertension</b> (page 246) (forskolin) <b>Obesity</b> (page 446) <b>Psoriasis</b> (page 379)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

As recorded in ancient Sanskrit texts, coleus was used in Ayurvedic medicine<sup>1</sup> to treat heart and lung diseases, intestinal spasms, **insomnia** (page 270), and convulsions.

#### **Active constituents**

Forskolin, a chemical found in coleus, activates the enzyme adenylate cyclase.<sup>2</sup> This enzyme is a turnkey compound that initiates a cascade of critical events within

every cell of the body. Adenylate cyclase and the chemicals it activates comprise a “second messenger” system that is responsible for carrying out the complex and powerful effects of hormones in the body. Stimulation of the second messenger system by forskolin leads to blood vessel dilation,<sup>3</sup> inhibition of allergic reactions,<sup>4</sup> and an increase in thyroid hormone secretion.<sup>5</sup> Forskolin has other properties as well, including inhibition of the pro-inflammatory substance known as platelet-activating factor (PAF)<sup>6</sup> and inhibition of the spread of cancer cells.<sup>7</sup>

Studies in healthy humans, including at least one double-blind trial, have shown that direct application of an ophthalmic preparation of forskolin to the eyes lowers eye pressure,<sup>8,9</sup> thus reducing the risk of **glaucoma** (page 205). Direct application of the whole herb to the eyes has not been studied and is not recommended.

Forskolin may help dilate blood vessels and improve the forcefulness with which the heart pumps blood. A preliminary trial found that forskolin reduced **blood pressure** (page 246) and improved heart function in people with **cardiomyopathy** (page 95).<sup>10</sup> It is unknown if oral coleus extracts would have the same effect. A small double-blind trial found that inhaled forskolin could decrease lung spasms in **asthmatics** (page 32).<sup>11</sup> It is unclear if oral ingestion of coleus extracts will provide similar benefits.

#### How much is usually taken?

Coleus extracts standardized to 10% to 18% forskolin are available. While some doctors expert in herbal medicine recommend 50–100 mg two to three times per day of standardized coleus extract, these amounts are extrapolations and have yet to be confirmed by direct clinical research.<sup>12</sup> Most studies have used injected forskolin, so it is unclear if oral ingestion of coleus extracts will provide similar benefits in the amounts recommended above. Until ophthalmic preparations of coleus or forskolin are available, people with glaucoma should consult with a skilled healthcare practitioner to obtain a sterile fluid extract for use in the eyes.

#### Are there any side effects or interactions?

Few adverse effects of coleus have been reported. It should be avoided in people with **ulcers** (page 349), because it may increase stomach acid levels. Direct application to the eyes may cause transitory tearing, burning, and itching. The safety of coleus in **pregnancy** (page 363) and breast-feeding is unknown.

## COLTSFOOT

**Botanical name:** *Tussilago farfara*

#### Parts used and where grown

The flowers, leaves, and roots of coltsfoot have been used as herbal medicines. However, the roots are generally avoided now. Coltsfoot originates in Eurasia and North Africa, and now also grows throughout damp areas of North America.

**Coltsfoot has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Cough</b> (page 139) <b>Sore throat</b> (page 129)

#### Historical or traditional use (may or may not be supported by scientific studies)

Coltsfoot historically has been used by herbalists to alleviate **coughs** (page 139) due to all manner of conditions. It was considered particularly useful for people with chronic coughs, such as those due to emphysema or silicosis.<sup>1</sup> Coltsfoot leaf was originally approved for the treatment of **sore throats** (page 129) in the German Commission E monograph<sup>2</sup> but has since been banned in Germany for internal use.<sup>3</sup>

#### Active constituents

Mucilage, bitter glycosides, and tannins are considered the major constituents of coltsfoot.<sup>4</sup> These are thought to give the herb anti-inflammatory and antitussive (cough prevention and treatment) activity.<sup>5</sup> Coltsfoot also contains pyrrolizidine alkaloids, potentially toxic constituents.

#### How much is usually taken?

Internal use of coltsfoot root is not recommended due to the potential liver toxicity of its pyrrolizidine alkaloids. Tea of coltsfoot leaf or flower is made by steeping 1–2 teaspoons (5–10 grams) in 1 cup (250 ml) hot water for ten to twenty minutes.<sup>6</sup> People can drink three cups (750 ml) daily. Alternatively, ½–1 teaspoon (2–4 ml) of tincture of the leaf or flower can be taken three times per day. Some practitioners of herbal medicine have recommended having hot coltsfoot tea ready in a thermos to drink for morning coughs due to em-

physema.<sup>7</sup> People should not use coltsfoot for more than one month consecutively unless on the advice of a doctor. Also, preparations guaranteed to be pyrrolizidine-free can be used indefinitely and are preferable.

#### **Are there any side effects or interactions?**

Coltsfoot contains potentially liver-damaging pyrrolizidine alkaloids, with much higher levels appearing in the root than in the leaves or the flowers. Animal studies using amounts of coltsfoot hundreds of times higher than those used as medicine have shown these alkaloids can cause cancer in animals.<sup>8</sup> A single case of an infant who developed liver disease and died after the mother drank tea containing coltsfoot during pregnancy has been reported.<sup>9</sup> This eventually led to the banning of coltsfoot in Germany in 1992.

Coltsfoot should not be taken during **pregnancy** (page 363) or breast-feeding.<sup>10</sup> Otherwise, coltsfoot is generally safe.<sup>11</sup>

Coltsfoot should be differentiated from the plant called western coltsfoot (*Petastites frigidus*), because western coltsfoot can contain higher amounts of pyrrolizidine alkaloids. Use of western coltsfoot is not recommended.

## **COMFREY**

**Common names:** Knitbone, boneset

**Botanical name:** *Symphytum officinale*

#### **Parts used and where grown**

The leaf and root of comfrey have been employed medicinally for centuries. Originally from Europe and western Asia, it is now also grown in North America.

**Comfrey has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Broken bones (topical) <b>Bruises</b> (page 84) (topical) Chronic skin ulcer (topical) <b>Conjunctivitis/blepharitis</b> (page 136) (topical eye application) <b>Cough</b> (page 139) <b>Peptic ulcer</b> (page 349) <b>Sprains</b> (page 412) (topical) Thrombophlebitis (topical) <b>Wound healing</b> (page 319) (topical)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Comfrey has a long history of use as a topical agent for treating **wounds** (page 319), skin ulcers, thrombophlebitis, **bruises** (page 84), and **sprains and strains** (page 412).<sup>1, 2</sup> Comfrey was used by herbalists to promote more rapid repair of broken bones, hence the common names boneset and knitbone. Topically, comfrey was also used to treat minor skin irritations and inflammation. It has also been used as a wash or topical application for eye irritations and for treating **conjunctivitis** (page 136). Internally, it was used to treat gastrointestinal problems, such as stomach **ulcers** (page 349) and **inflammatory bowel disease** (page 269), and lung problems.

#### **Active constituents**

Mucilage and allantoin are considered the major constituents in comfrey responsible for the herbs soothing and anti-inflammatory actions.<sup>3</sup>

#### **How much is usually taken?**

Fresh, peeled root or dried root, approximately 3.5 ounces (100 grams), is simmered in 1 pint (500 ml) of water for ten to fifteen minutes to prepare comfrey for topical use.<sup>4</sup> Cloth or gauze is soaked in this liquid, then applied to the skin for at least 15 minutes. Fresh leaves can be ground up lightly and applied directly to the skin. Alternatively, creams or ointments made from root or leaf can be applied. All topical preparations should be applied several times per day.

Due to variations in pyrrolizidine alkaloid content, root preparations are unsafe for internal use unless they are guaranteed pyrrolizidine-free. Although comfrey root tea has been used traditionally, the danger of its pyrrolizidine alkaloids is significant. Therefore, comfrey root and young leaf preparations should not be taken internally.

#### **Are there any side effects or interactions?**

Comfrey contains potentially dangerous compounds known as pyrrolizidine alkaloids. The roots contain higher levels of these compounds and mature leaves contain very little, if any, of these alkaloids.<sup>5, 6</sup> Fresh young leaves contain higher amounts (up to 16 times more than mature leaves) and should be avoided.<sup>7</sup> Other related forms, such as Russian comfrey (*Symphytum uplandicum*) and prickly comfrey (*S. asperum*), are sometimes available or mistakenly sold as regular comfrey but contain higher levels of these alkaloids.<sup>8</sup> Several

cases of people who developed liver disease or other serious problems from taking capsules or tea of comfrey have been reported over the years.<sup>9</sup>

Most comfrey products do not list their pyrrolizidine alkaloid content on the label. Therefore, it is best to avoid internal use of products made from comfrey root or young leaves altogether.

### Special United Kingdom considerations

Comfrey for internal use is only available as an herbal tea, unless prescribed by a Medicinal Herbalist. People should consult with a qualified herbalist for other forms of this herb.

## CORDYCEPS

**Common names:** Caterpillar fungus, deer fungus parasite, chongcao

**Botanical name:** *Cordyceps* spp.

### Parts used and where grown

*Cordyceps sinensis* in its sexual stage is the primary form used.<sup>1</sup> However, more than ten related species (in sexual and asexual stages) as well as artificially cultured mycelium are today used as substitutes in commercial preparations. *C. sinensis*, *C. ophioglossoides*, *C. capitata*, and *C. militaris* are the most common species in commerce.

**Cordyceps has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Chronic hepatitis B</b> (page 220) Kidney disease
★☆☆	<b>Immune function</b> (page 255) Liver disease

### Historical or traditional use (may or may not be supported by scientific studies)

In ancient China, cordyceps was used in the Emperor's palace and was considered to have ginseng-like properties.<sup>2</sup> It was used to strengthen the body after exhaustion or long-term illness, and for impotence, neurasthenia, and backache. It was also used to cure opium addiction.

### Active constituents

*Cordyceps* contains a wide variety of potentially important constituents, including polysaccharides, ophiocordin (an antibiotic compound), cordycepin, cordypyridones, nucleosides, bioxanthracenes, sterols, alkenoic acids, and exo-polymers.<sup>3, 4, 5, 6, 7, 8, 9</sup>

Many studies on the medicinal effects of *cordyceps* do not give a clear picture of its actions because many of the studies (1) are in animals or test tubes; (2) use different species, preparations, and intake levels; (3) inject *cordyceps* and/or its constituents rather than administering them orally; or (4) are not available in English and, therefore, cannot be reviewed for accuracy and design.

There are some clinical trials supporting the efficacy of *cordyceps*, particularly for liver, kidney, and immune problems. A number of studies indicate that *cordyceps* may have anti-cancer, anti-metastatic, immuno-enhancing, and antioxidant effects.<sup>10, 11, 12, 13, 14</sup>

### How much is usually taken?

The recommended intake of *cordyceps* is 3 to 9 grams taken twice daily as a liquid extract, as food, or as powdered extract.<sup>15</sup>

### Are there any side effects or interactions?

There are insufficient studies on the safety of *cordyceps*. However, it has a long history of use as a food and is generally considered safe.<sup>16</sup> There is no information available about safety in pregnancy, lactation, or use in children.

There are two reported cases of lead poisoning associated with the use of apparently contaminated *cordyceps* powder.<sup>17</sup> *Cordyceps* should only be purchased from companies that test to exclude heavy metal contamination.

## CORYDALIS

**Common name:** Yan hu so

**Botanical names:** *Corydalis turtschaninovii*, *Corydalis yanhusuo*

### Parts used and where grown

*Corydalis* is an herb native to the Chinese province of Zhejiang. The portion of the plant that is used medicinally is the tuberous rhizome.<sup>1</sup>

**Corydalis has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Insomnia</b> (page 270) <b>Pain</b> (page 338) (nerve)
★★★	<b>Dysmenorrhea</b> (page 171) (painful menstruation) <b>Heart arrhythmia</b> (page 93) <b>Peptic ulcer</b> (page 349)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

In Traditional Chinese Medicine, corydalis is said to invigorate the blood, move qi (energy that travels through the body), and alleviate **pain** (page 338), including menstrual, abdominal, and hernial.<sup>2</sup>

#### **Active constituents**

Scientists have isolated a number of alkaloids from the tuber of corydalis, including corydaline, tetrahydropalmatine (THP), dl-Tetrahydropalmatine (dl-THP), protopine, tetrahydrocoptisine, tetrahydrocolumbamine, and corybulbine.<sup>3</sup> Of the full range of 20 alkaloids found in the plant, THP is considered to be the most potent. In laboratory research, it has been shown to exhibit a wide number of pharmacological actions on the central nervous system, including analgesic and sedative effects.<sup>4</sup> dl-THP has been found to exhibit a tranquilizing action in mice. Scientists have suggested that dl-THP blocks certain receptor sites (e.g., dopamine) in the brain to cause sedation.<sup>5</sup>

In addition to its central nervous system effects, studies in the laboratory have shown the alkaloids from corydalis also have cardiovascular actions. For example, dl-THP has been shown to both decrease the stickiness of platelets and protect against **stroke** (page 419),<sup>6</sup> as well as lower **blood pressure** (page 246) and heart rate in animal studies.<sup>7</sup> Additionally, it seems to exert an anti-arrhythmic action on the heart. This was found in a small double-blind clinical trial with patients suffering from a specific type of **heart arrhythmia** (page 93) (e.g., supra-ventricular premature beat or SVPB).<sup>8</sup> People taking 300–600 mg of dl-THP per day in tablet form, had a significantly greater improvement than those taking placebo pills.

Other human clinical trials on dl-THP have shown the ability to fall asleep was improved in people suffer-

ing from **insomnia** (page 270) after taking 100–200 mg of dl-THP at bedtime. No drug hangover symptoms such as morning grogginess, dizziness or **vertigo** (page 441) were reported by people taking the alkaloid extract.<sup>9</sup>

Reports from Chinese researchers also note that 75 mg of THP daily was effective in reducing nerve pain in 78% of the patients tested.<sup>10</sup> Painful menstruation (**dysmenorrhea** [page 171]), abdominal pain after childbirth, and headache have also been reported to be successfully treated with THP.<sup>11</sup>

Extracts of the herb may also be useful in the treatment of **stomach ulcers** (page 349). In a large sample of patients with stomach and intestinal ulcers or chronic inflammation of the stomach lining, a 90–120 mg extract of the herb per day (equal to 5–10 grams of the crude herb) was found to improve healing and symptoms in 76% of the patients.<sup>12</sup>

#### **How much is usually taken?**

For an analgesic or sedative effect, the crude, dried rhizome is usually recommended at 5–10 grams per day.<sup>13</sup> Alternatively, one can take 10–20 ml per day of a 1:2 extract.<sup>14</sup>

#### **Are there any side effects or interactions?**

Corydalis should not be taken by **pregnant** (page 363) or nursing women.<sup>15</sup> There have been several reports in Western journals of THP toxicity, including acute **hepatitis** (page 220).<sup>16, 17, 18</sup> In addition, people taking corydalis can experience **vertigo** (page 441), fatigue, and nausea.<sup>19</sup>

## CRANBERRY

**Botanical name:** *Vaccinium macrocarpon*

#### **Parts used and where grown**

Cranberry is a member of the same family as **bilberry** (page 634) and blueberry. It is from North America and grows in bogs. The ripe fruit is used medicinally.

**Cranberry has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Urinary tract infection</b> (page 436) prevention

### **Historical or traditional use (may or may not be supported by scientific studies)**

In traditional North American herbalism, cranberry has been used to prevent **kidney stones** (page 284) and “bladder gravel” as well as to remove toxins from the blood. Cranberry has long been recommended by herbalists as well as doctors to help prevent **urinary tract infections** (page 436) (UTIs).

### **Active constituents**

In test tube studies, cranberry prevents *E. coli*, the most common bacterial cause of UTIs, from adhering to the cells lining the wall of the bladder. This anti-adherence action is thought to reduce the ability of the bacteria to cause a UTI.<sup>1,2</sup> The **proanthocyanidins** (page 574) in the berry have exhibited this anti-adherence action.<sup>3</sup> Cranberry has been shown to reduce bacteria levels in the urinary bladders of older women significantly better than placebo, an action that may help to prevent UTIs.<sup>4</sup> A small double-blind trial with younger women ages 18–45 years with a history of recurrent **urinary tract infections** (page 436), found that daily treatment with an encapsulated cranberry concentrate (400 mg twice per day) for three months significantly reduced the recurrence of urinary tract infections compared to women taking a placebo.<sup>5</sup> Other preliminary trials in humans suggest cranberry may help people with urostomies and enterocystoplasties to keep their urine clear of mucus buildup and possibly reduce the risk of UTIs.<sup>6</sup> However, one trial found that cranberry did not reduce the risk of UTIs in children with neurogenic bladder disease (a condition that does not allow for proper flow of urine from the bladder) who were receiving daily catheterization.<sup>7</sup>

### **How much is usually taken?**

One capsule of concentrated cranberry juice extract (400 mg) can be taken two times per day.<sup>8</sup> Several 16-ounce (500 ml) glasses of high-quality unsweetened cranberry juice from concentrate each day approximate the effect of the cranberry extract. Cranberry tincture,  $\frac{1}{2}$ –1 teaspoon (3–5 ml) three times per day, can also be taken.

### **Are there any side effects or interactions?**

Cranberry concentrate has not been reported to cause side effects and has no known contraindications to use during **pregnancy** (page 363) and **breast-feeding** (page 74). According to one report, supplementation with an unspecified number of cranberry tablets for seven days

increased the urinary excretion of oxalate by 43%, suggesting that long term use of cranberry supplements might increase the risk of developing a **kidney stone** (page 284).<sup>9</sup> On the other hand, in the same study, urinary excretion of magnesium and potassium (which are inhibitors of stone formation) also increased. Until more is known, individuals with a personal or family history of calcium-oxalate kidney stones should consult a doctor before using cranberry supplements for long periods of time (e.g., more than a week). Cranberry should not be used as a substitute for antibiotics during an acute **urinary tract infection** (page 436), except under medical supervision.

## **CRANESBILL**

**Botanical name:** *Geranium maculatum*

### **Parts used and where grown**

Cranesbill originated in North America and is sometimes grown ornamenteally in a variety of flower colors. The root is primarily used in herbal medicine, but the above-ground part of the plant has also been used traditionally by herbalists.

**Cranesbill has been used in connection with the following conditions** (refer to the individual health concern for complete information):

<b>Rating</b>	<b>Health Concerns</b>
★☆☆	<b>Canker sores</b> (page 90) <b>Crohn's disease</b> (page 141) <b>Diarrhea</b> (page 163) <b>Menorrhagia</b> (page 314)

### **Historical or traditional use (may or may not be supported by scientific studies)**

The Blackfoot Indians of North America used the root of cranesbill and closely related plants to stop bleeding.<sup>1</sup> Cranesbill has also been used by other indigenous tribes of North America to treat **diarrhea** (page 163).

### **Active constituents**

Cranesbill is high in tannins, which may account for its anti-diarrheal activity.<sup>2</sup> Little scientific research exists to clarify cranesbill's constituents and actions.

### How much is usually taken?

A tea can be prepared by boiling 1–2 teaspoons (5–10 grams) of the root for ten to fifteen minutes in 2 cups (500 ml) of water.<sup>3</sup> People can drink three (750 ml) or more cups per day. Cranesbill tincture (approximately  $\frac{1}{2}$  teaspoon or 3 ml) three times per day is also commonly used, although generally in combination with other herbs, for **diarrhea** (page 163). Dried, powdered cranesbill root is sometimes used in an herbal combination to treat **Crohn's disease** (page 141); however, there are no scientific studies to support this combination.

### Are there any side effects or interactions?

Cranesbill tea should not be used for more than two to three consecutive weeks. Due to the high tannin content, some people may develop an upset stomach after using cranesbill.

## DAMIANA

**Botanical name:** *Turnera diffusa*

### Parts used and where grown

The leaves of damiana were originally used as medicine by the indigenous cultures of Central America, particularly Mexico. Today the plant is found in hot, humid climates, including Mexico and parts of Texas, the Caribbean, and southern Africa.

**Damiana has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Depression</b> (page 145) <b>Erectile dysfunction</b> (page 185)

### Historical or traditional use (may or may not be supported by scientific studies)

Damiana has been hailed as an aphrodisiac since ancient times, particularly by the native peoples of Mexico.<sup>1</sup> Other folk uses have included **asthma** (page 32), **bronchitis** (page 80), neurosis, and various sexual disorders.<sup>2</sup> It has also been promoted as a euphoria-inducing substance.

### Active constituents

Most research has been done on the volatile oil of damiana, which includes numerous small, fragrant substances called terpenes.<sup>3</sup> As yet, it is unclear if the volatile oil is truly the main active constituent of damiana. Damiana extracts have been shown, in a test tube, to weakly bind to **progesterone** (page 577) receptors.<sup>4</sup> Thus, damiana may be a potentially useful herb for some female health problems. However, no human studies have investigated this possibility and it is not a primary traditional use.

### How much is usually taken?

To make a tea, add 1 cup (250 ml) boiling water to  $\frac{1}{4}$  teaspoon (1 gram) of dried leaves and allow to steep for ten to fifteen minutes. People can drink three cups (750 ml) per day. To use in tincture form, take  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (2–3 ml) three times daily. Tablets or capsules (400–800 mg three times per day) may also be used. Damiana is commonly used in herbal combinations. However, the authors of the German Commission E monographs do not feel that traditional use of this herb is justified by modern research.<sup>5</sup>

### Are there any side effects or interactions?

The leaves have a minor laxative effect and may cause loosening of the stools at higher amounts. Until more is known about damiana's effects on the female hormonal system, it should be avoided during **pregnancy** (page 363).<sup>6</sup>

## DANDELION

**Botanical name:** *Taraxacum officinale*

### Parts used and where grown

Closely related to chicory, dandelion is a common plant worldwide and the bane of those looking for the perfect lawn. The plant grows to a height of about 12 inches, producing spatula-like leaves and yellow flowers that bloom year-round. Upon maturation, the flower turns into the characteristic puffball containing seeds that are dispersed in the wind. Dandelion is grown commercially in the United States and Europe. The leaves and root are used in herbal supplements.

**Dandelion has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Constipation</b> (page 137) (root) <b>Edema (water retention)</b> (page 180) (leaves) <b>Indigestion and heartburn</b> (page 260) (leaves and root) Liver support (root) <b>Pregnancy and postpartum support</b> (page 363) (leaves and root)

### Historical or traditional use (may or may not be supported by scientific studies)

Dandelion is commonly used as a food. The leaves are used in salads and teas, while the roots are sometimes used as a coffee substitute. Dandelion leaves and roots have been used for hundreds of years to treat liver, gallbladder, kidney, and joint problems. In some traditions, dandelion is considered a blood purifier and is used for conditions as varied as **eczema** (page 177) and **cancer** (page 87). As is the case today, dandelion leaves have also been used historically to treat **water retention** (page 180).

### Active constituents

The primary constituents responsible for dandelion's action on the digestive system and liver are the bitter principles. Previously referred to as taraxacin, these constituents are sesquiterpene lactones of the eudesmanolide and germacranolide type, and are unique to dandelion.<sup>1</sup> Dandelion is also a rich source of vitamins and minerals. The leaves have a high content of **vitamin A** (page 595) as well as moderate amounts of **vitamin D** (page 607), **vitamin C** (page 604), various **B vitamins** (page 603), **iron** (page 540), **silicon** (page 586), **magnesium** (page 551), **zinc** (page 614), and **manganese** (page 553).<sup>2</sup>

An animal study found that at high amounts (2 grams per 2.2 pounds [1 kg] of body weight), the leaves possess diuretic effects comparable to the prescription diuretic furosemide (Lasix).<sup>3</sup> However, to date, these results have not been demonstrated in human clinical trials. Since **edema** (page 180), or water retention, may be a sign of a more serious disease, people should seek the guidance of a physician before using dandelion leaves for either of these conditions.

The bitter compounds in the leaves and root help stimulate digestion and are mild laxatives.<sup>4</sup> These bitter principles also increase bile production in the gallbladder and bile flow from the liver.<sup>5</sup> For this reason dandelion is recommended by some herbalists for people with sluggish liver function due to alcohol abuse or poor diet. The increase in bile flow may help improve fat (including cholesterol) metabolism in the body.

### How much is usually taken?

As a general liver/gallbladder tonic and to stimulate digestion,  $\frac{1}{2}$ –1 teaspoon (3–5 grams) of the dried root or 1–2 teaspoons (5–10 ml) of a tincture made from the root can be used three times per day.<sup>6</sup> Some experts recommend the alcohol-based tincture because the bitter principles are more soluble in alcohol.<sup>7</sup>

As a mild diuretic or appetite stimulant, 1–2 teaspoons (4–10 grams) of dried leaves can be added to a 1 cup (250 ml) of boiling water and drunk as a decoction.<sup>8</sup> Or, 1–2 teaspoons (5–10 ml) of fresh juice or  $\frac{1}{2}$ –1 teaspoon (2–5 ml) of tincture made from the leaves can be used three times per day. Fresh dandelion leaves can be eaten as part of a salad.

### Are there any side effects or interactions?

Dandelion leaf and root should not be used by people with **gallstones** (page 193) without the supervision of a healthcare practitioner.<sup>9</sup> People with an obstruction of the bile ducts should not take dandelion. In cases of stomach **ulcer** (page 349) or **gastritis** (page 195), dandelion should be used cautiously, as it may cause over-production of stomach acid. Those experiencing fluid or water retention should consult a doctor before taking dandelion leaves. The milky latex in the stem and leaves of fresh dandelion may cause an allergic rash in some people.

Dandelion root contains approximately 40% inulin,<sup>10</sup> a fiber widely distributed in fruits, vegetables and plants. Inulin is classified as a food ingredient (not as an additive) and is considered to be safe to eat.<sup>11</sup> In fact, inulin is a significant part of the daily diet of most of the world's population.<sup>12</sup> However, there is a report of a 39-year old man having a life-threatening allergic reaction after consuming high amounts of inulin from multiple sources.<sup>13</sup> Allergy to inulin in this individual was confirmed by laboratory tests. Such sensitivities are exceedingly rare. Moreover, this man did not take dandelion. Nevertheless, people with a confirmed sensitivity to inulin should avoid dandelion.

## DEVIL'S CLAW

**Botanical name:** *Harpagophytum procumbens*

### Parts used and where grown

Devil's claw is a native plant of southern Africa, especially the Kalahari desert, Namibia and the island of Madagascar. The name devil's claw is derived from the herb's unusual fruits, which are covered with numerous small claw-like appendages. The secondary storage roots, or tubers, of the plant are used in herbal supplements.<sup>1</sup>

**Devil's claw has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Osteoarthritis</b> (page 328) <b>Rheumatoid arthritis</b> (page 387)
★★★☆	<b>Indigestion</b> (page 260) <b>Low back pain</b> (page 293)

### Historical or traditional use (may or may not be supported by scientific studies)

Numerous tribes native to southern Africa have used devil's claw for a wide variety of conditions, ranging from gastrointestinal difficulties to arthritic conditions.<sup>2</sup> Devil's claw has been widely used in Europe as a treatment for arthritis.

### Active constituents

The devil's claw tuber contains three important constituents belonging to the iridoid glycoside family: harpagoside, harpagide, and procumbide. The secondary tubers of the herb contain twice as much harpagoside as the primary tubers and are the chief source of devil's claw used medicinally.<sup>3</sup> Harpagoside and other iridoid glycosides found in the plant may be responsible for the herb's anti-inflammatory and analgesic actions. However, research has not entirely supported the use of devil's claw in alleviating arthritic pain symptoms.<sup>4,5</sup> In one trial it was found to reduce pain associated with **osteoarthritis** (page 328) as effectively as the slow-acting analgesic/cartilage-protective drug diacerhein.<sup>6</sup> One double-blind study reported that devil's claw (600 or 1200 mg per day) was helpful in reducing **low back pain** (page 293).<sup>7</sup>

Devil's claw is also considered by herbalists to be a potent bitter. Bitter principles, like the iridoid glycosides found in devil's claw, can be used in combination with carminative (gas-relieving) herbs by people with **indigestion** (page 260), but not **heartburn** (page 260).

### How much is usually taken?

As a digestive stimulant, 1.5–2 grams per day of the powdered secondary tuber are used.<sup>8</sup> For tincture, the recommended amount is 1–2 ml three times daily. For **osteoarthritis** (page 328) and **rheumatoid arthritis** (page 387), 4.5–10 grams of powder are used per day. Alternatively, standardized extracts, 1,200–2,500 mg per day, may be taken.

### Are there any side effects or interactions?

Since devil's claw promotes the secretion of stomach acid, anyone with gastric or duodenal **ulcers** (page 349), **heartburn** (page 260), **gastritis** (page 195), or excessive stomach acid should not use the herb. Additionally, people with **gallstones** (page 193) should consult a physician before taking devil's claw.<sup>9</sup>

## DONG QUAI

**Common names:** Dang-gui, Chinese angelica

**Botanical name:** *Angelica sinensis*

### Parts used and where grown

Dong quai is a member of the celery family. Greenish-white flowers bloom from May to August, and the plant is typically found growing in damp mountain ravines, meadows, river banks, and coastal areas. The root is used in herbal medicine.

**Dong quai has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Anemia (due to dialysis)
	<b>Dysmenorrhea</b> (page 171) (painful menstruation)
	<b>Menopause</b> (page 311)
	<b>Premenstrual syndrome</b> (page 368)

### Historical or traditional use (may or may not be supported by scientific studies)

Also known as dang-gui in Traditional Chinese Medicine (TCM), dong quai is sometimes referred to as the female ginseng. In Traditional Chinese Medicine, dong quai is often included in herbal combinations for abnormal menstruation, suppressed menstrual flow, **dysmenorrhea** (page 171) (painful menstruation), and uterine bleeding. It is not used in TCM for treating symptoms associated with **menopause** (page 311), such as hot flashes. It is also used in TCM for both men and women with **cardiovascular disease** (page 98), including **high blood pressure** (page 246) and problems with peripheral circulation.<sup>1</sup>

### Active constituents

Traditionally, dong quai is believed to have a balancing or “adaptogenic” effect on the female hormonal system. Contrary to the opinion of some authors, dong quai does not qualify as a phytoestrogen and does not appear to have any hormone-like actions in the body. This is partially supported by a double-blind trial with **menopausal** (page 311) women that found no estrogenic activity for the herb.<sup>2</sup> In Traditional Chinese Medicine, dong quai is rarely used alone and is typically used in combination with herbs such as peony and ligusticum for conditions such as menstrual cramps.<sup>3</sup>

Dong quai has been traditionally used as a way to promote formation of red blood cells, an effect partially supported in a case study of a man with kidney failure who had a significant improvement in anemia due to dialysis while drinking a tea composed of dong quai and peony.<sup>4</sup> No clinical trials have examined dong quai alone for this purpose, or for the treatment of other forms of anemia.

### How much is usually taken?

The powdered root can be used in capsules or tablets.<sup>5</sup> Women may take 3–4 grams daily in three divided applications. Alternatively, 3–5 ml of tincture may be taken three times per day.

### Are there any side effects or interactions?

Dong quai may cause some fair-skinned people to become more sensitive to sunlight. People using it on a regular basis should limit prolonged exposure to the sun or other sources of ultraviolet radiation. Dong quai is not recommended for **pregnant** (page 363) or breastfeeding women.<sup>6</sup>

## ECHINACEA

**Common name:** Purple coneflower

**Botanical names:** *Echinacea purpurea*, *Echinacea angustifolia*, *Echinacea pallida*

### Parts used and where grown

Echinacea is a wildflower native to North America. While echinacea continues to grow and is harvested from the wild, the majority used for herbal supplements comes from cultivated plants. The root and/or the above-ground part of the plant during the flowering growth phase are used in herbal medicine.

**Echinacea has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Common cold/sore throat</b> (page 129) (for symptoms; effective only for adults)
★★☆	<b>Gingivitis</b> (page 203) (periodontal disease) (as mouthwash, in combination with <b>sage</b> [page 740], <b>peppermint</b> [page 726] oil, menthol, <b>chamomile</b> [page 656] tincture, <b>myrrh</b> [page 713] tincture, clove oil, and <b>caraway oil</b> [page 651]) <b>Immune function</b> (page 255) <b>Infection</b> (page 265) <b>Influenza</b> (page 269)
★☆☆	<b>Bronchitis</b> (page 80) <b>Canker sores</b> (page 90) <b>Chronic candidiasis</b> (page 109) <b>Cold sores</b> (page 119) <b>Ear infections (recurrent)</b> (page 383) <b>Gingivitis (periodontal disease)</b> (page 203) <b>HIV support</b> (page 239) <b>Pap smear (abnormal)</b> (page 3) <b>Vaginitis</b> (page 438) <b>Wound healing</b> (page 319) (topical) <b>Yeast infection</b> (page 454)

### Historical or traditional use (may or may not be supported by scientific studies)

Echinacea was used by Native Americans for a variety of conditions, including venomous bites and other external wounds. It was introduced into U.S. medical practice in 1887 and was touted for use in conditions ranging from **colds** (page 129) to syphilis. Modern research started in the 1930s in Germany.

### Active constituents

Echinacea is thought to support the **immune system** (page 255) by activating white blood cells.<sup>1</sup> Three major groups of constituents may work together to increase the production and activity of white blood cells (lymphocytes and macrophages), including alkylamides/polyacetylenes, caffeic acid derivatives, and polysaccharides. More studies are needed to determine if and how echinacea stimulates the immune system in humans.

Echinacea may also increase production of interferon, an important part of the body's response to viral infections.<sup>2</sup> Several double-blind studies have confirmed the benefit of echinacea for treating **colds** (page 129) and **flu** (page 269).<sup>3, 4, 5, 6, 7</sup> Recent studies have suggested that echinacea may not be effective for the prevention of colds and flu and should be reserved for use at the onset of these conditions.<sup>8, 9</sup> In terms of other types of infections, research in Germany using injectable forms or an oral preparation of the herb along with a medicated cream (econazole nitrate) reduced the recurrence of vaginal **yeast infections** (page 454) as compared to women given the cream alone.<sup>10</sup>

### How much is usually taken?

At the onset of a cold or flu, 3–4 ml of echinacea in a liquid preparation or 300 mg of a powdered form in capsule or tablet, can be taken every two hours for the first day of illness, then three times per day for a total of 7 to 10 days.<sup>11</sup>

### Are there any side effects or interactions?

Echinacea is rarely associated with side effects when taken orally.<sup>12</sup> According to the German Commission E monograph, people should not take echinacea if they have an autoimmune illness, such as **lupus** (page 421), or other progressive diseases, such as tuberculosis, **multiple sclerosis** (page 323), or **HIV** (page 239) infection. However, the concern about echinacea use for those with autoimmune illness is not based on clinical research and some herbalists question the potential connection. Those who are allergic to flowers of the daisy family should not take echinacea. Cases of allergic responses to echinacea (e.g., wheezing, skin rash, **diarrhea** [page 163]) have been reported in medical literature.<sup>13</sup> In the first study to look at echinacea's possible effect on fetal development and pregnancy outcome, women taking echinacea during **pregnancy** (page 363) were found to have no greater incidence of miscarriage or **birth defects** (page 63) than women not taking the herb.<sup>14</sup>

Echinacea root contains approximately 20% inulin,<sup>15</sup> a fiber widely distributed in fruits, vegetables, and plants. Inulin is classified as a food ingredient (not as an additive) and is considered safe to eat.<sup>16</sup> In fact, inulin is a significant part of the daily diet of most of the world's population.<sup>17</sup> However, there is a report of a 39-year-old man having a life-threatening allergic reaction after consuming high amounts of inulin from multiple sources.<sup>18</sup> Allergy to inulin in this individual was confirmed by laboratory tests. Such sensitivities are exceedingly rare. Moreover, this man did not take echinacea. Nevertheless, people with a confirmed sensitivity to inulin should avoid echinacea.

## ELDERBERRY

**Common names:** European elderberry (black elderberry), North American elderberry

**Botanical name:** *Sambucus nigra*

### Parts used and where grown

Numerous species of elder or elderberry grow in Europe and North America. Only those with blue/black berries are medicinal. The flowers and berries are both used. Species with red berries are not medicinal.

**Elderberry has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	Influenza (page 269)
★☆☆	Cold sores (page 119) Common cold/sore throat (page 129) Infection (page 265) Inflammation

### Historical or traditional use (may or may not be supported by scientific studies)

Elderberries have long been used as food, particularly in the dried form. Elderberry wine, pie, and lemonade are some of the popular ways to prepare this plant as food. The leaves were touted by European herbalists to be pain relieving and to promote healing of injuries when applied as a poultice.<sup>1</sup> Native American herbalists used the plant for **infections** (page 265), **coughs** (page 139), and skin conditions.

### Active constituents

**Flavonoids** (page 516), including **quercetin** (page 580), are believed to account for the therapeutic actions of the elderberry flowers and berries. These flavonoids include anthocyanins that are powerful **antioxidants** (page 467) and protect cells against damage according to test tube studies.<sup>2</sup> According to laboratory research, an extract from the leaves, combined with **St. John's wort** (page 747) and soapwort, inhibits the **influenza** (page 269) virus and **herpes simplex** (page 119) virus.<sup>3</sup> The effect on influenza of a syrup made from the berries of the black elderberry has been studied in a small double-blind trial.<sup>4</sup> People receiving an elderberry extract (2 tablespoons [30 ml] per day for children, 4 tablespoons [60 ml] per day for adults) appeared to recover faster than did those receiving a placebo. Animal studies have shown the flowers to have anti-inflammatory properties.<sup>5</sup> These actions have not been verified in human clinical trials.

### How much is usually taken?

A syrup of black elderberry extract (1 teaspoon–1 tablespoon [5–15 ml] for children, 2 teaspoons–2 tablespoons [10–30 ml] for adults) can be taken twice daily. A tea made from  $\frac{1}{2}$ –1 teaspoon (3–5 grams) of the dried flowers steeped in 1 cup (250 ml) boiling water for ten to fifteen minutes may be drunk three times per day.<sup>6</sup>

### Are there any side effects or interactions?

The safe internal use of elderberry is limited to the use of the dried flowers or syrups made from the ripe berries.<sup>7</sup> The roots, stems, leaves, and unripe berries may contain poisonous constituents that can cause nausea, vomiting, and **diarrhea** (page 163).<sup>8</sup> Preparations containing any of these parts of the elder plant should be avoided.

## ELECAMPANE

**Common name:** Inula

**Botanical name:** *Inula helenium*

### Parts used and where grown

Elecampsane is indigenous to Europe and Asia and is now grown in the United States. The dried roots and rhizomes (branching part of the root) are collected in fall or early winter and used in herbal preparations.

**Elecampsane has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Asthma</b> (page 32) <b>Bronchitis</b> (page 80) <b>Chronic obstructive pulmonary disease</b> (page 114) (COPD) <b>Cough</b> (page 139) <b>Indigestion</b> (page 260)

### Historical or traditional use (may or may not be supported by scientific studies)

Traditionally, herbalists have used elecampsane to treat **coughs** (page 139), particularly those associated with **bronchitis** (page 80), **asthma** (page 32), and whooping cough.<sup>1</sup> The herb has also been used historically to treat poor digestion and general complaints of the intestinal tract.

### Active constituents

Elecampsane root and rhizome contain approximately 1–4% volatile oils.<sup>2</sup> Most of these volatile oils are composed of sesquiterpene lactones, including alantolactone. Elecampsane is also very high in inulin (44%)<sup>3</sup> and mucilage. Most herbal texts attribute the actions of elecampsane to alantolactone.<sup>4</sup> The antitussive (cough prevention and treatment) and carminative (soothing effect on the intestinal tract) effects of elecampsane, however, may possibly be due to the inulin and mucilage content. Isolated alantolactone has been used to treat **parasites** (page 343) (e.g., roundworm, threadworm, hookworm, whipworm). This use is only by prescription and is not approved in all European countries.<sup>5</sup>

### How much is usually taken?

The German Commission E Monograph states the historical application of elecampsane has not been adequately proven to recommend its use.<sup>6</sup> This is partially based on the potential side effects listed below. For traditional use, elecampsane is typically recommended as a tea. Boiling water is poured over  $\frac{1}{4}$  teaspoon (1 gram) of the ground root and rhizome, left to steep for ten to fifteen minutes, then strained. One cup of this preparation is taken three to four times daily. Some texts recommend  $\frac{1}{2}$  to 1 teaspoon (3–5 ml) of a tincture three times daily.<sup>7</sup>

### Are there any side effects or interactions?

The inulin in elecampsane root is widely distributed in fruits, vegetables and plants. It is classified as a food in-

gradient (not as an additive) and is considered safe to eat.<sup>8</sup> In fact, inulin is a significant part of the daily diet of most of the world's population.<sup>9</sup> However, there is a report of a 39-year-old man having a life-threatening allergic reaction after consuming high amounts of inulin from multiple sources.<sup>10</sup> Allergy to inulin in this individual was confirmed by laboratory tests. Such sensitivities are extremely rare. Moreover, this man did not take elecampane. Nevertheless, people with a confirmed sensitivity to inulin should avoid elecampane.

Alantolactone can be an irritant to the intestinal tract and, along with other sesquiterpene lactones in elecampane, may cause localized irritation in the mouth. Amounts several times higher than those stated above may cause vomiting, **diarrhea** (page 163), spasms, and signs of paralysis.<sup>11</sup> If these symptoms occur, people should contact their local poison control center. **Pregnant** (page 363) or nursing women should not use elecampane.

## ELEUTHERO

**Common names:** Siberian ginseng, ci wu jia, touch-me-not, devil's shrub

**Botanical names:** *Eleutherococcus senticosus*, *Acanthopanax senticosus*

### Parts used and where grown

Eleuthero belongs to the Araliaceae family and is a distant relative of **Asian ginseng** (page 630) (*Panax ginseng*). Also known commonly as touch-me-not and devil's shrub, eleuthero has been most frequently nicknamed Siberian ginseng in this country. Eleuthero is native to the Taiga region of the Far East (southeastern part of Russia, northern China, Korea, and Japan). The root and the rhizomes (underground stem) are used medicinally.

**Eleuthero has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Athletic performance</b> (page 43) Fatigue <b>Immune function</b> (page 255) Stress

★★☆

- Breast cancer** (page 65)
- Chronic fatigue syndrome** (page 111)
- Common cold/sore throat** (page 129)
- Diabetes** (page 152)
- HIV support** (page 239)
- Infection** (page 265)
- Influenza** (page 269)

### Historical or traditional use (may or may not be supported by scientific studies)

Although not as popular as **Asian ginseng** (page 630), eleuthero use dates back 2,000 years, according to Chinese medicine records. Referred to as ci wu jia in Chinese medicine, it was used to prevent respiratory tract infections, **colds** (page 129) and **flu** (page 269). It was also believed to provide energy and vitality. In Russia, eleuthero was originally used by people in the Siberian Taiga region to increase performance and quality of life and to decrease **infections** (page 265).

In more modern times, eleuthero has been used to increase stamina and endurance in Soviet Olympic athletes. Russian explorers, divers, sailors, and miners also used eleuthero to prevent stress-related illness. After the Chernobyl accident, many Russian and Ukrainian citizens were given eleuthero to counteract the effects of radiation.

### Active constituents

The constituents in eleuthero that have been most studied are the eleutherosides.<sup>1</sup> Seven primary eleutherosides have been identified, with most of the research attention focusing on eleutherosides B and E.<sup>2</sup> Eleuthero also contains complex polysaccharides (complex sugar molecules).<sup>3</sup> These constituents may play a critical role in eleuthero's ability to support **immune function** (page 255).

Eleuthero is an "adaptogen" (an agent that helps the body adapt to stress). It is thought to help support adrenal gland function when the body is challenged by stress.<sup>4</sup>

Eleuthero has been shown to enhance mental acuity and physical endurance without the letdown that comes with caffeinated products.<sup>5</sup> Research has shown that eleuthero improves the use of oxygen by the exercising muscle.<sup>6</sup> This means that a person is able to maintain aerobic **exercise** (page 43) longer and recover from workouts more quickly. Preliminary research from Russia indicates it may be effective for this purpose.<sup>7</sup> Other trials have been inconclusive<sup>8</sup> or have shown no beneficial effect.<sup>9</sup>

Eleuthero may also support the body by helping the liver detoxify harmful toxins. It has shown a protective action in animal studies against chemicals such as ethanol, sodium barbital, tetanus toxoid, and chemotherapeutic agents.<sup>10</sup> According to a test tube study eleuthero also helps protect the body during radiation exposure.<sup>11</sup> Preliminary research in Russia has suggested that eleuthero may help alleviate side effects and help the bone marrow recover more quickly in people undergoing chemotherapy and radiation therapy for cancer (page 87).<sup>12</sup>

Eleuthero may be useful as a preventive measure during the **cold** (page 129) and **flu** (page 269) season. However, it has not yet been specifically studied for this purpose. Preliminary evidence also suggests that eleuthero may prove valuable in the long-term management of various diseases of the immune system, including **HIV** (page 239) infection and **chronic fatigue syndrome** (page 111). Healthy people taking 2 teaspoons (10 ml) of tincture three times daily have been shown to have increased numbers of the immune cells (T4 lymphocytes) that have been found to decrease during HIV-infection and AIDS.<sup>13</sup> Further human clinical trials are needed to confirm that eleuthero may be helpful for this disease.

#### **How much is usually taken?**

Dried, powdered root and rhizomes, 2–3 grams per day, are commonly used.<sup>14</sup> Alternatively, 300–400 mg per day of concentrated solid extract standardized on eleutherosides B and E can be used, as can alcohol-based extracts, 8–10 ml in two to three divided dosages. Historically, eleuthero is taken continuously for six to eight weeks, followed by a one- to two-week break before resuming.

#### **Are there any side effects or interactions?**

Reported side effects have been minimal with use of eleuthero.<sup>15</sup> Mild, transient **diarrhea** (page 163) has been reported in a very small number of users. Eleuthero may cause **insomnia** (page 270) in some people if taken too close to bedtime. Eleuthero is not recommended for people with uncontrolled **high blood pressure** (page 246). There are no known reasons to avoid eleuthero during **pregnancy** (page 363) and breast-feeding. However, pregnant or breast-feeding women should be aware that some products may be adulterated with herbs that should *not* be taken in pregnancy, such as **Asian ginseng** (page 630). Only eleuthero from a trusted source should be used.

In one case report, a person taking eleuthero with digoxin developed dangerously high serum digoxin levels.<sup>16</sup> Although a clear relationship could not be established, it is wise for someone taking digoxin to seek the advise of a doctor before taking eleuthero.

## EUCALYPTUS

**Botanical name:** *Eucalyptus globulus*

#### **Parts used and where grown**

Eucalyptus is an evergreen tree native to Australia but is cultivated worldwide. The plant's leaves—and the oil that is steam-distilled from them—are used medicinally.<sup>1</sup>

**Eucalyptus has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Insect repellant (topical)
★☆☆	<b>Athletic performance</b> (page 43) (topical) <b>Bronchitis</b> (page 80) <b>Chronic obstructive pulmonary disease</b> (page 114) (COPD) <b>Common cold</b> (page 129) <b>Cough</b> (page 139) <b>Genital herpes</b> (page 200) (topical) <b>Infection</b> (page 265) <b>Low back pain</b> (page 293) Rheumatism (topical use) <b>Rheumatoid arthritis</b> (page 387) (oil, topical) <b>Sinus congestion</b> (page 405) <b>Sinusitis</b> (page 407)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Eucalyptus was first used by Australian aborigines, who not only chewed the roots for water in the dry outback but used the leaves as a remedy for fevers. In the 1800s, crew members of an Australian freighter developed high fevers, but were able to successfully cure their condition using eucalyptus tea. Thus, eucalyptus became well known throughout Europe and the Mediterranean as the Australian fever tree. Early 19th century Eclectic physicians in the United States not only used eucalyptus oil to sterilize instruments and wounds, but recommended a steam inhalation of the vapor of its oil to help

treat **asthma** (page 32), **bronchitis** (page 80), whooping cough, and emphysema.<sup>2</sup>

### Active constituents

The major constituent in eucalyptus leaves is a volatile oil known as eucalyptol (1,8-cineol). In order to provide an effective expectorant and antiseptic action, the leaf oil should contain approximately 70–85% eucalyptol.<sup>3</sup> Eucalyptus oil is said to function in a fashion similar to that of menthol by acting on receptors in the nasal mucosa, leading to a reduction in symptoms such as **nasal congestion** (page 405).<sup>4</sup> In test tube studies, eucalyptus species have been shown to possess antibacterial actions against such organisms as *Bacillus subtilis*,<sup>5</sup> as well as several strains of *Streptococcus*.<sup>6</sup> These actions have not been researched in human clinical trials.

**Peppermint** (page 726) (10 grams) and eucalyptus oil (5 grams) in combination, applied topically to the forehead and temples for three minutes with a small sponge, have been shown to be helpful as a muscle relaxant (but not for pain relief) in people with tension headaches.<sup>7</sup> A eucalyptus oil extract containing 50% p-methane-3,8-diol (PMD) as the active ingredient has been shown to be effective in protecting human volunteers from various types of biting insects.<sup>8</sup> On human forearms, it was determined that the eucalyptus extract was nearly as effective as a 20% solution of diethyltoluamine (used in many insect repellents) in repelling bites of the *Anopheles* mosquito (the insect that spreads malaria) for up to five hours. The eucalyptus extract was also effective at repelling flies (94%) and midges (100%) for up to six hours.

A preliminary study suggests the combination of eucalyptus and menthol as a nasal inhalant is helpful in cases of mild to moderate snoring.<sup>9</sup> Also, in a double-blind trial, a eucalyptus-based rub was found helpful for warming muscles in athletes.<sup>10</sup> This further suggests eucalyptus may help relieve minor muscle soreness when applied topically, though studies are needed to confirm this possibility.

### How much is usually taken?

Eucalyptus oil (0.05–0.2 ml per day) can be taken internally by adults.<sup>11</sup> It should always be diluted in warm water before consuming. For local applications, 30 ml of the oil can be mixed in 500 ml of lukewarm water and applied topically as an insect repellent or used over the temporal areas of the forehead for tension headaches. As an inhalant, add a few drops of eucalyptus oil to hot water or a vaporizer. Deeply inhale the

steam vapor. For eucalyptus leaf preparations, an infusion of 2–3 grams of the chopped leaves may be boiled in 150 ml of water and taken two times per day. Eucalyptus oil needs to be used very cautiously since as little as 3.5 ml of the oil taken internally has proven fatal.<sup>12</sup> It is best for people to discuss internal use with a qualified healthcare professional.

---

**Warning:** Eucalyptus oil needs to be used very cautiously since as little as 3.5 ml of the oil taken internally has proven fatal. It is best for individuals to discuss internal use with a qualified healthcare professional.

---

### Are there any side effects or interactions?

Side effects from the internal use of eucalyptus can include nausea, vomiting, and **diarrhea** (page 163). Eucalyptus oil should not be used by infants and children under the age of two, especially near the face and nose, due to the risk of airway spasm and possible cessation of breathing.<sup>13</sup> The oil may aggravate bronchial spasms in people with **asthma** (page 32) and should not be taken internally by those with severe liver diseases and inflammatory disorders of the gastrointestinal tract and kidney.<sup>14, 15</sup> Whole-body application of eucalyptus oil (double-distilled, containing 80–85% cineole oil) resulted in severe nervous system toxicity in a six year old girl.<sup>16</sup> Parents are advised to use topical eucalyptus oil in moderation with children.

Although there are no known reports of drug interactions, the German Commission E monograph suggests that because eucalyptus oil may activate certain enzyme systems in the liver, it may potentially weaken or shorten the action of some medications, including pentobarbital, aminopyrine, and amphetamine.<sup>17, 18</sup> Eucalyptus should not be used in large amounts by people with low blood pressure as it may cause a further drop in blood pressure.<sup>19</sup> The safety of eucalyptus oil has not been established in **pregnant** (page 363) or nursing women.

## EYEBRIGHT

**Botanical name:** *Euphrasia officinalis*

### Parts used and where grown

In the wild, European eyebright grows in meadows, pastures, and grassy places in Bulgaria, Hungary, and the

former Yugoslavia. Eyebright is also grown commercially in Europe. The plant flowers in late summer and autumn. The whole herb is used in herbal medicine.

**Eyebright has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Conjunctivitis/blepharitis</b> (page 136) Irritated eyes

**Historical or traditional use (may or may not be supported by scientific studies)**

Eyebright was and continues to be used by herbalists primarily as a poultice for the topical treatment of eye inflammations, including **conjunctivitis/blepharitis** (page 136) and sties. Traditionally, a compress made from a decoction of eyebright is used to give relief from redness, swelling, and visual disturbances due to eye **infections** (page 265).<sup>1</sup> A tea is sometimes given internally along with the topical treatment. It has also been used for the treatment of eye fatigue and other disturbances of vision. In addition, herbalists have recommended eyebright for problems of the respiratory tract, including **sinus infections** (page 407), **coughs** (page 139), and **sore throat** (page 129).<sup>2</sup> None of the traditional uses of eyebright have been studied in clinical research.

**Active constituents**

While there are many chemicals that may be active in eyebright, none of them has been proven to have any effect on eye inflammation or irritation. Some herbal texts suggest that the astringent actions of eyebright may reduce eye irritation while others suggest that eyebright may also have antibacterial actions topically. To date, there are no clinical studies to support or refute these proposed actions.

**How much is usually taken?**

Traditional herbal texts recommend a compress made with 1 tablespoon (15 grams) of the dried herb combined with 2 cups (500 ml) of water and boiled for ten minutes.<sup>3</sup> The undiluted liquid is used as a compress after cooling. The German Commission E monograph does not support this application, due to possible impurities in non-pharmaceutical preparations.<sup>4</sup> Consult with a physician knowledgeable in the use of herbs before applying eyebright to the eyes.

Internally, two to three cups per day of eyebright tea is sometimes recommended. Dried herb,  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (2–4 grams) three times per day, may also be taken. The tincture is typically taken in  $\frac{1}{2}$ – $1\frac{1}{2}$  teaspoons (2–6 ml) three times per day.

**Are there any side effects or interactions?**

Due to limited information on the active constituents in eyebright and the need for sterility in substances used topically in the eyes, the traditional use of eyebright as a topical compress currently cannot be recommended without professional support. Used internally at the amounts listed above, eyebright is generally safe. However, its safety during **pregnancy** (page 363) and breastfeeding has not been proven.

## FALSE UNICORN

**Botanical name:** *Chamaelirium luteum*

**Parts used and where grown**

False unicorn is native to Mississippi and continues to grow primarily in the southern part of the United States. The roots of false unicorn are most commonly used in herbal medicine.

**False unicorn has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Dysmenorrhea</b> (page 171) (painful menstruation)

**Historical or traditional use (may or may not be supported by scientific studies)**

The medicinal use of false unicorn root is based in traditional Native American herbalism. It was recommended for many women's health conditions, including **dysmenorrhea** (page 171) (painful menstruation) and other irregularities of menstruation, as well as to prevent miscarriages.<sup>1</sup> False unicorn was also used as a remedy for **morning sickness** (page 320).

**Active constituents**

Steroidal saponins are generally credited with providing false unicorn root's activity.<sup>2</sup> However, modern investi-

gations have not confirmed this, and no research exists about the medical applications of this herb.

#### How much is usually taken?

False unicorn root tincture,  $\frac{1}{2}$ –1 teaspoon (2–5 ml) three times per day, is sometimes recommended.<sup>3</sup> The dried root,  $\frac{1}{2}$ – $\frac{1}{4}$  teaspoon (1–2 grams) three times per day, is also used.

#### Are there any side effects or interactions?

No adverse effects have been reported with the use of false unicorn. Although false unicorn has been used historically for nausea and vomiting of pregnancy and to prevent miscarriages, its actions as a possible uterine tonic make its use during **pregnancy** (page 363) potentially unsafe.

## FENNEL

**Botanical name:** *Foeniculum vulgare*

#### Parts used and where grown

The fennel plant came originally from Europe, where it is still grown. Fennel is also cultivated in many parts of North America, Asia, and Egypt. Fennel seeds are used in herbal medicine.

**Fennel has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Colic</b> (page 121) (in combination with <b>chamomile</b> [page 656], <b>verbena</b> [page 756], <b>licorice</b> [page 702] and <b>lemon balm</b> [page 701]) <b>Colic</b> (page 121) (fennel seed oil) <b>Indigestion and heartburn</b> (page 260)
★☆☆	<b>Irritable bowel syndrome</b> (page 280)

#### Historical or traditional use (may or may not be supported by scientific studies)

According to the Greek legend of Prometheus, fennel was thought to have bestowed immortality.<sup>1</sup> Fennel seeds are a common cooking spice, particularly for use with fish. After meals, they are used in several cultures to prevent gas and upset stomach.<sup>2</sup> Fennel has also been

used as a remedy for **cough** (page 139) and **colic** (page 121) in infants.

#### Active constituents

The major constituents, which include the terpenoid anethole, are found in the volatile oil. Anethole and other terpenoids inhibit spasms in smooth muscles,<sup>3</sup> such as those in the intestinal tract, and this is thought to contribute to fennel's use as a carminative (gas-relieving and gastrointestinal tract cramp-relieving agent). Related compounds to anethole may have mild estrogenic actions, although this has not been proven in humans. Fennel is also thought to possess diuretic (increase in urine production), choleric (increase in production of bile), pain-reducing, fever-reducing, and anti-microbial actions.<sup>4</sup> Fennel was formerly an official drug in the United States and was listed as being used for **indigestion** (page 260).<sup>5</sup>

#### How much is usually taken?

The German Commission E monograph recommends 1–1½ teaspoons (5–7 grams) of seeds per day.<sup>6</sup> To make a tea, boil  $\frac{1}{2}$  teaspoon (2–3 grams) of crushed seeds per 1 cup (250 ml) of water for ten to fifteen minutes, keeping the pot covered during the process. Cool, strain, and then drink three cups (750 ml) per day. As a tincture, 1–2 teaspoons (5–10 ml) can be taken three times per day between meals.

#### Are there any side effects or interactions?

No significant adverse effects have been reported. However, in rare cases fennel can cause allergic reactions of the skin and respiratory tract.<sup>7</sup> Anyone with an estrogen-dependent **cancer** (page 87) (e.g., some **breast cancer** (page 65) patients) should avoid fennel in large quantities until the significance of its estrogen-like activity is clarified.

## FENUGREEK

**Botanical name:** *Trigonella foenum-graecum*

#### Parts used and where grown

Although originally from southeastern Europe and western Asia, fenugreek grows today in many parts of the world, including India, northern Africa, and the United States. The seeds of fenugreek are used medicinally.

**Fenugreek has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Diabetes</b> (page 152) <b>High cholesterol</b> (page 223)
★★☆	<b>Atherosclerosis</b> (page 38) <b>High triglycerides</b> (page 235)
★☆☆	<b>Constipation</b> (page 137)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

A wide range of uses were found for fenugreek in ancient times. Medicinally it was used for the treatment of **wounds** (page 319), abscesses, arthritis, **bronchitis** (page 80), and digestive problems. Traditional Chinese herbalists used it for kidney problems and conditions affecting the male reproductive tract.<sup>1</sup> Fenugreek was, and remains, a food and a spice commonly eaten in many parts of the world.

#### **Active constituents**

Fenugreek seeds contain alkaloids (mainly trigonelline) and protein high in **lysine** (page 550) and L-tryptophan. Its steroidal saponins (diosgenin, yamogenin, tigogenin, and neotigogenin) and mucilaginous **fiber** (page 512) are thought to account for many of the beneficial effects of fenugreek. The steroidal saponins are thought to inhibit cholesterol absorption and synthesis,<sup>2</sup> while the fiber may help lower blood sugar levels.<sup>3</sup> One human study found that fenugreek can help lower **cholesterol** (page 223) and blood sugar levels in people with moderate **atherosclerosis** (page 38) and non-insulin-dependent (type 2) **diabetes** (page 152).<sup>4</sup> Preliminary and double-blind trials have found that fenugreek helps improve blood sugar control in patients with insulin-dependent (type 1) and non-insulin-dependent (type 2) diabetes.<sup>5, 6, 7</sup> Double-blind trials have shown that fenugreek lowers elevated cholesterol and **triglyceride** (page 235) levels in the blood.<sup>8, 9</sup> This has also been found in a controlled clinical trial with diabetic patients with elevated cholesterol.<sup>10</sup> Generally, fenugreek does not lower HDL ("good") cholesterol levels.

#### **How much is usually taken?**

Due to the somewhat bitter taste of fenugreek seeds, de-bitterized seeds or encapsulated products are pre-

ferred. The German Commission E monograph recommends a daily intake of 6 grams.<sup>11</sup> The typical range of intake for **diabetes** (page 152) or **cholesterol** (page 223)-lowering is 5–30 grams with each meal or 15–90 grams all at once with one meal. As a tincture, 3–4 ml of fenugreek can be taken up to three times per day.

#### **Are there any side effects or interactions?**

Use of more than 100 grams of fenugreek seeds daily can cause intestinal upset and nausea. Otherwise, fenugreek is extremely safe. Due to the potential uterine stimulating properties of fenugreek, which may cause miscarriages, fenugreek should not be used during **pregnancy** (page 363).<sup>12</sup>

## FEVERFEW

**Botanical name:** *Tanacetum parthenium*

#### **Parts used and where grown**

Feverfew grows widely across Europe and North America. The leaves are used in herbal medicine.

**Feverfew has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Migraine headaches</b> (page 316)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Feverfew was mentioned in Greek medical literature as a remedy for inflammation and for menstrual discomforts. Traditional herbalists in Great Britain used it to treat fevers, rheumatism, and other aches and pains.

#### **Active constituents**

Feverfew contains a range of compounds known as sesquiterpene lactones. Over 85% of these are a compound called parthenolide. In test tube studies, parthenolide prevents excessive clumping of platelets and inhibits the release of certain chemicals, including serotonin and some inflammatory mediators.<sup>1, 2</sup> Feverfew's parthenolide content was originally thought to ac-

count for the anti-migraine action of this herb, but this has been a matter of recent debate.<sup>3</sup>

According to three double-blind trials with migraine patients, feverfew reduces the severity, duration, and frequency of **migraine headaches** (page 316).<sup>4, 5, 6</sup> These successful studies employed dried, powdered leaves. One negative study used an alcohol extract suggesting the dried leaf preparation is superior.<sup>7</sup>

### How much is usually taken?

Feverfew leaf products with at least 0.2% parthenolide content are generally used. Standardized leaf extracts may contain up to 0.7% parthenolide. Herbal products in capsules or tablets providing at least 250 mcg of parthenolide per day may be taken.<sup>8</sup> It may take four to six weeks before benefits are noticed. Feverfew is useful for decreasing the severity and incidence of migraines. However, it is not an effective treatment for an acute migraine attack.

### Are there any side effects or interactions?

Taken as recommended, standardized feverfew causes minimal side effects. Minor side effects include gastrointestinal upset and nervousness. Chewing feverfew leaves has been reported to cause **canker sores** (page 90).<sup>9</sup> Feverfew is not recommended during **pregnancy** (page 363) or breast-feeding and should not be used by children under the age of two years.

## FO-TI

**Common name:** He-shou-wu

**Botanical name:** *Polygonum multiflorum*

### Parts used and where grown

Fo-ti is a plant native to China, where it continues to be widely grown. It also grows extensively in Japan and Taiwan. The unprocessed root is sometimes used medicinally. However, once it has been boiled in a special liquid made from black beans, it is considered a superior and rather different medicine according to Traditional Chinese Medicine. The unprocessed root is sometimes called white fo-ti and the processed root red fo-ti. According to Chinese herbal medicine, the unprocessed root is used to relax the bowels and detoxify the blood, and the processed root is used to strengthen the blood, invigorate the kidneys and liver, and serve as a tonic to increase overall vitality.

**Fo-ti has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Constipation</b> (page 137) <b>High cholesterol</b> (page 223) <b>Immune function</b> (page 255)

### Historical or traditional use (may or may not be supported by scientific studies)

The Chinese common name for fo-ti, he-shou-wu, was the name of a Tang dynasty man whose infertility was supposedly cured by fo-ti. In addition, his long life was attributed to the tonic properties of this herb.<sup>1</sup> Since then, Traditional Chinese Medicine has used fo-ti to treat premature aging, weakness, vaginal discharges, numerous infectious diseases, **angina pectoris** (page 27), and **erectile dysfunction** (page 185).

### Active constituents

The major constituents of fo-ti are anthraquinones, phospholipids (e.g., lecithin), tannins, and tetrahydroxystilbene glucoside. The processed root has been used to lower cholesterol levels in Traditional Chinese Medicine. According to animal research, it helps to decrease fat deposits in the blood and possibly prevent **atherosclerosis** (page 38).<sup>2, 3</sup> However, human clinical trials are lacking to support this use. Test tube studies have suggested fo-ti's ability to stimulate **immune function** (page 255), increase red blood cell formation, and exert an antibacterial action.<sup>4</sup> None of these effects has been studied in humans. The unprocessed roots have a mild laxative action.

### How much is usually taken?

The typical recommended intake is 1–1½ teaspoons (4–8 grams) per day.<sup>5</sup> A tea can be made from processed roots by boiling ½–1 teaspoons (3–5 grams) in 1 cup (250 ml) of water for ten to fifteen minutes. Three or more cups are suggested each day. Five fo-ti tablets (500 mg each) can be taken three times per day.

### Are there any side effects or interactions?

The unprocessed roots may cause mild **diarrhea** (page 163).<sup>6</sup> Some people who are sensitive to fo-ti may develop a skin rash. Taking more than 15 grams of processed root powder may cause numbness in the arms or legs.

## GARLIC

**Botanical name:** *Allium sativum*

### Parts used and where grown

Garlic has been used since time immemorial as a culinary spice and medicinal herb. Garlic has been cultivated in the Middle East for more than 5,000 years and has been an important part of Traditional Chinese Medicine. The region with the largest commercial garlic production is central California. China is also a supplier of commercial garlic. The bulb is used medicinally.

**Garlic has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Atherosclerosis</b> (page 38)
★★☆	<b>BPH</b> (page 58) (Kastamonu Garlic) <b>Breast-feeding support</b> (page 74) <b>Colon cancer</b> (page 123) (reduces risk of stomach, esophageal, and colon cancers) <b>Common cold</b> (page 129) <b>High blood pressure</b> (page 246) <b>High cholesterol</b> (page 223) <b>High triglycerides</b> (page 235) <b>Intermittent claudication</b> (page 276) <b>Warts</b> (page 445) (topical application)
★☆☆	<b>Athlete's foot</b> (page 42) <b>Chronic candidiasis</b> (page 109) <b>Ear infections (recurrent)</b> (page 383) <b>HIV support</b> (page 239) <b>Infection</b> (page 265) <b>Parasites</b> (page 343) <b>Peptic ulcer</b> (page 349) <b>Sickle cell anemia</b> (page 403)

### Historical or traditional use (may or may not be supported by scientific studies)

Garlic is mentioned in the Bible and the Talmud. Hippocrates, Galen, Pliny the Elder, and Dioscorides all mention the use of garlic for many conditions, including **parasites** (page 343), respiratory problems, poor digestion, and low energy. Its use in China was first mentioned in A.D. 510. Louis Pasteur studied the antibacterial action of garlic in 1858.

### Active constituents

The sulfur compound allicin, produced by crushing or chewing fresh garlic or by taking powdered garlic prod-

ucts with allicin potential, in turn produces other sulfur compounds: ajoene, allyl sulfides, and vinylidithiins.<sup>1</sup> Aged garlic products lack allicin, but may have activity due to the presence of S-allylcysteine.

Many publications have shown that garlic supports the cardiovascular system. While earlier trials suggest it may mildly lower **cholesterol** (page 223) and **triglyceride** (page 235) levels in the blood,<sup>2, 3, 4</sup> more recent trials found garlic to have minimal success in lowering cholesterol and triglycerides.<sup>5, 6, 7</sup> Garlic also inhibits platelet stickiness (aggregation) and increases fibrinolysis,<sup>8</sup> which results in a slowing of blood coagulation. It is mildly **antihypertensive** (page 246)<sup>9</sup> and has **antioxidant** (page 467) activity.<sup>10</sup>

Garlic's cardiovascular protective effects were illustrated in a four-year clinical trial on people 50–80 years old with **atherosclerosis** (page 38).<sup>11</sup> It was found that consumption of 900 mg of a standardized garlic supplement reduced arterial plaque formation by 5–18%. The benefits were most notable in women.

In test tube studies garlic has been found to have antibacterial, antiviral, and antifungal activity.<sup>12</sup> However, these actions are less clear in humans and do not suggest that garlic is a substitute for antibiotics or antifungal medications.

Human population studies suggest that eating garlic regularly reduces the risk of esophageal, stomach, and **colon cancer** (page 123).<sup>13, 14</sup> This may be partly due to garlic's ability to reduce the formation of carcinogenic compounds.

### How much is usually taken?

People who wish to consume garlic and have no aversion to its odor can chew from one to two whole cloves of raw garlic daily. For those who prefer it with less odor, enteric-coated tablets or capsules with approximately 1.3% allin are available. Clinical trials have used 600–900 mg (delivering approximately 5,000–6,000 mcg of allicin potential) per day in two or three divided amounts.<sup>15, 16</sup> Aged-garlic extracts have been studied in amounts ranging from 2.4–7.2 grams per day.

### Are there any side effects or interactions?

Many people enjoy eating garlic. However, some people who are sensitive to it may experience **heartburn** (page 260) and flatulence. Because of garlic's anti-clotting properties, people taking anticoagulant drugs should check with their doctor before taking garlic.<sup>17</sup> Those scheduled for surgery should inform their surgeon if they are taking garlic supplements. Garlic appears to be

safe during **pregnancy** (page 363) and breast-feeding. In fact, two studies have shown that babies like breast milk better from mothers who eat garlic.<sup>18, 19</sup>

## GENTIAN

**Botanical name:** *Gentiana lutea*

### Parts used and where grown

Gentian originally comes from meadows in Europe and Turkey. However, it is now also cultivated in North America. The root is used in herbal medicine.

**Gentian has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Indigestion</b> (page 260) Poor appetite <b>Sinusitis</b> (page 407) (in combination with primrose flowers, sorrel herb, elder flowers, and European <b>verbain</b> [page 756])

### Historical or traditional use (may or may not be supported by scientific studies)

Gentian root and other highly bitter plants have been used for centuries by herbalists in Europe as digestive aids (the well-known Swedish bitters often contain gentian). Other folk uses included topical application on skin tumors, decreasing fevers, and treatment of **diarrhea** (page 163).<sup>1</sup>

### Active constituents

Gentian contains bitter substances such as the glycosides gentiopicrin and amarogentin. The bitter taste of these can be detected even when diluted 50,000 times.<sup>2</sup> Besides stimulating secretion of saliva in the mouth and hydrochloric acid in the stomach, gentiopicrin may protect the liver.<sup>3</sup> Gentian is used to treat poor appetite and **indigestion** (page 260).<sup>4</sup> An open study shows that gentian tincture inhibits the feeling of fullness after eating, suggesting it could improve poor appetite.<sup>5</sup>

### How much is usually taken?

Tincture can be taken 20 minutes before each meal, for a total of  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–3 ml) daily. Alternatively, whole root,  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (2–4 grams) per day, can be used. Since capsules of the herb bypass the taste buds, they may not have the same effect as other dosage methods.

## Are there any side effects or interactions?

Gentian should not be used by people suffering from excessive stomach acid, **heartburn** (page 260), **peptic ulcer disease** (page 349), or **gastritis** (page 195).<sup>6</sup>

## GINGER

**Botanical name:** *Zingiber officinale*

### Parts used and where grown

Ginger is a perennial plant that grows in India, China, Mexico, and several other countries. The rhizome (underground stem) is used as both a spice and in herbal medicine.

**Ginger has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Motion sickness</b> (page 322) <b>Osteoarthritis</b> (page 328)
★☆☆	<b>Epilepsy</b> (page 183) (in combination with <b>bupleurum</b> [page 647], peony root, <b>pinellia</b> root, <b>cassia bark</b> , <b>jujube fruit</b> , <b>Asian ginseng</b> [page 630] root, <b>Chinese scullcap</b> [page 658] root, and <b>licorice</b> [page 702] root) <b>Indigestion</b> (page 260) <b>Irritable bowel syndrome</b> (page 280) (Chinese herbal combination formula containing <b>wormwood</b> [page 762], ginger, <b>bupleurum</b> [page 647], <b>schisandra</b> [page 744], dan shen, and other extracts) <b>Morning sickness</b> (page 320) Nausea and vomiting following <b>surgery</b> (page 357) Nausea following chemotherapy <b>Pre- and post-surgery health</b> (page 357) <b>Vertigo</b> (page 441)
★☆☆	<b>Atherosclerosis</b> (page 38) <b>Hay fever</b> (page 211) (Sho-seiryu-to: contains <b>licorice</b> [page 702], <b>cassia bark</b> , <b>schisandra</b> [page 744], <b>ma huang</b> [ephedra], ginger, peony root, <b>pinellia</b> , and <b>asiasarum root</b> ) <b>HIV support</b> (page 239) (in combination with <b>bupleurum</b> [page 647], peony root, <b>pinellia</b> root, <b>cassia bark</b> , <b>ginger root</b> , <b>jujube fruit</b> , <b>Asian ginseng</b> [page 630] root, <b>Chinese scullcap</b> [page 658] root, and <b>licorice</b> [page 702] root) <b>Low back pain</b> (page 293) <b>Migraine headaches</b> (page 316) <b>Rheumatoid arthritis</b> (page 387)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Traditional Chinese Medicine has recommended ginger for over 2,500 years. It is used for abdominal bloating, **coughing** (page 139), vomiting, **diarrhea** (page 163), and rheumatism. Ginger is commonly used in the Ayurvedic and Tibb systems of medicine for the treatment of inflammatory joint diseases, such as arthritis and rheumatism.

### **Active constituents**

The dried rhizome of ginger contains approximately 1–4% volatile oils. These are the medically active constituents of ginger and are also responsible for ginger's characteristic odor and taste. The aromatic constituents include zingiberene and bisabolene, while the pungent constituents are known as gingerols and shogaols.<sup>1</sup> The pungent constituents are credited with the anti-nausea and anti-vomiting effects of ginger.

In humans, ginger is thought to act directly on the gastrointestinal system to reduce nausea.<sup>2</sup> Ginger has been shown to reduce the symptoms of **motion sickness** (page 322) associated with travel by boat and, to a lesser extent, car.<sup>3, 4, 5</sup> Two double-blind clinical trials have found that ginger may reduce nausea due to anesthesia following surgery,<sup>6, 7</sup> although one trial could not confirm this benefit.<sup>8</sup> A preliminary trial has suggested ginger may be helpful for preventing chemotherapy-induced nausea.<sup>9</sup>

While ginger is a popular remedy for **nausea of pregnancy** (page 320), it has only been clinically studied for very severe nausea and vomiting known as hyperemesis gravidarum.<sup>10</sup> This condition is life threatening and should only be treated by a qualified healthcare professional. Because ginger contains some compounds that cause chromosomal mutation in the test tube, some doctors are concerned about the safety of using ginger during pregnancy. However, the available clinical research, combined with the fact that ginger is widely used in the diet of certain cultures, suggests that prudent use of ginger for morning sickness is safe in amounts up to 1 gram per day.

Ginger is considered a tonic for the digestive tract, stimulating digestion and toning the intestinal muscles.<sup>11</sup> This action eases the transport of substances through the digestive tract, lessening irritation to the intestinal walls.<sup>12</sup> Ginger may protect the stomach from the damaging effect of alcohol and non-steroidal anti-inflammatory drugs (NSAIDs, such as ibuprofen) and may help prevent **ulcers** (page 349).<sup>13</sup>

Ginger also supports **cardiovascular health** (page 98). Ginger may make blood platelets less sticky and

less likely to aggregate.<sup>14, 15</sup> However, not all human research has confirmed this.<sup>16, 17</sup>

### **How much is usually taken?**

For prevention or treatment of motion sickness, 500 mg of dried ginger powder can be taken one-half to one hour before travel, and then 500 mg every two to four hours as necessary. Children below the age of six should use one-half the adult amount. For the treatment of nausea associated with **pregnancy** (page 320), women can take up to 1 gram daily,<sup>18</sup> but should only use ginger for symptomatic relief of nausea and not on an ongoing basis. Ginger may potentially be used for nausea associated with anesthesia or chemotherapy, but only under the supervision of a physician.

### **Are there any side effects or interactions?**

Side effects due to ginger are rare when used as recommended. However, some people sensitive to the taste may experience **heartburn** (page 260). People with a history of **gallstones** (page 193) should consult a doctor before using ginger.<sup>19</sup> Short-term use of ginger for nausea and vomiting during **pregnancy** (page 320) appears to pose no safety problems. However, long-term use during pregnancy is not recommended. A doctor should be informed if ginger is used before surgery as the herb may increase bleeding.

## **GINKGO BILOBA**

**Common name:** Maidenhair tree

**Botanical name:** *Ginkgo biloba*

### **Parts used and where grown**

*Ginkgo biloba* is the world's oldest living species of tree. Individual trees live as long as 1,000 years. *Ginkgo* grows most predominantly in the southern and eastern United States, southern France, China, and Korea. The leaves of the tree are used in modern herbal medicine.

***Ginkgo biloba* has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Age-related cognitive decline</b> (page 8) (ARCD) <b>Alzheimer's disease</b> (page 19) (early-stage) <b>Glaucoma</b> (page 205) (normal tension glaucoma) <b>Intermittent claudication</b> (page 276)

Rating	Health Concerns
★★☆	Altitude sickness (prevention) <b>Depression</b> (page 145) (for elderly people) <b>Erectile dysfunction</b> (page 185) (of vascular origin) <b>Macular degeneration</b> (page 303) <b>Schizophrenia</b> (page 393) (in combination with haloperidol) <b>Vertigo</b> (page 441) <b>Vitiligo</b> (page 443)
★★★	<b>Asthma</b> (page 32) <b>Atherosclerosis</b> (page 38) Deafness, acute cochlear <b>Diabetes</b> (page 152) Memory enhancement (in healthy adults) <b>Ménière's disease</b> (page 308) <b>Migraine headaches</b> (page 316) <b>Multiple sclerosis</b> (page 323) (injections) <b>Premenstrual syndrome</b> (page 368) <b>Raynaud's disease</b> (page 382) <b>Retinopathy</b> (page 385) <b>Tinnitus</b> (page 430)

### Historical or traditional use (may or may not be supported by scientific studies)

Medicinal use of ginkgo can be traced back almost 5,000 years in Chinese herbal medicine. The nuts of the tree were most commonly recommended and used to treat respiratory tract ailments. The use of the leaves is a modern development originating in Europe.

### Active constituents

The medical benefits of *Ginkgo biloba* extract (GBE) are attributed primarily to two groups of active constituents: the ginkgo flavone glycosides and the terpene lactones. Ginkgo flavone glycosides, which typically make up approximately 24% of the extract, are primarily responsible for GBE's **antioxidant** (page 467) activity and may mildly inhibit platelet aggregation (stickiness). These two actions may help GBE prevent circulatory diseases, such as **atherosclerosis** (page 38), and support the brain and central nervous system.<sup>1</sup> In addition to the cardiovascular system, GBE's antioxidant action may also extend to the brain and retina of the eye.<sup>2</sup> Preliminary trials have suggested potential benefit for people with **macular degeneration** (page 303)<sup>3</sup> and **diabetic retinopathy** (page 385).<sup>4</sup> The terpene lactones found in GBE, known as ginkgolides and bilobalide, typically make up approximately 6% of the extract. They are associated with increasing circulation to the brain and other parts of the body and may exert

a protective action on nerve cells.<sup>5</sup> GBE regulates the tone and elasticity of blood vessels,<sup>6</sup> making circulation more efficient.<sup>7</sup>

Ginkgo is also well-known for its effect on memory and thinking (cognitive function). It may enhance cognitive performance in healthy older adults,<sup>8</sup> in people with **age-related cognitive decline** (page 8), and in people with **Alzheimer's disease** (page 19).

### How much is usually taken?

Most clinical trials have used between 120 and 240 mg of GBE (standardized to contain 6% terpene lactones and 24% flavone glycosides) per day, generally divided into two or three portions.<sup>9</sup> The higher amount (240 mg per day) has been used in some people with mild-to-moderate **Alzheimer's disease** (page 19), **age-related cognitive decline** (page 8), **intermittent claudication** (page 276), and resistant **depression** (page 145). GBE may need to be taken for eight to twelve weeks before desired actions such as cognitive improvement are noticed. Although nonstandardized *Ginkgo biloba* leaf and tinctures are available, there is no well-established amount or use for these forms.

### Are there any side effects or interactions?

Excessive bleeding has been reported in a few individuals taking GBE,<sup>10, 11</sup> although a cause/effect relationship was not proven. In addition, two elderly individuals with well-controlled epilepsy developed recurrent seizures within two weeks after starting GBE.<sup>12</sup> Mild headaches lasting for a day or two and mild upset stomach have been reported in a small number of people using GBE.

Ginkgo leaves are known to contain a group of potentially toxic constituents known as alkylphenols. The ginkgo extracts known as EGb 761 and LI 1370 have been shown to conform to the safety limits for these constituents (less than 5 ppm), as set forth by the German Commission E. Other forms of ginkgo may contain higher concentrations of alkylphenols.<sup>13</sup>

One small clinical trial found that ginkgo supplementation for three months increased secretion of insulin by the pancreas, but did not affect blood glucose levels, in healthy young adults.<sup>14</sup> These results suggest that the participants may have developed an insensitivity to insulin, a potential concern because insulin insensitivity may be a precursor to type 2 **diabetes** (page 152). However, this trial does not prove that ginkgo causes insulin insensitivity, nor does it prove that long-term ginkgo supplementation increases the risk for any

disease. In addition, the results of this trial are not consistent with other research on ginkgo. Larger and more rigorously designed clinical trials of ginkgo supplementation have found no significant adverse effects after as many as 12 months of supplementation.<sup>15</sup>

People should seek an accurate medical diagnosis prior to self-prescribing GBE. This is especially important for the elderly, whose circulatory conditions can involve serious disease, and for people scheduled for surgery, as GBE may affect bleeding time.

## GOLDENSEAL

**Botanical name:** *Hydrastis canadensis*

### Parts used and where grown

Goldenseal is native to eastern North America and is cultivated in Oregon and Washington. It is seriously threatened by over-harvesting in the wild. The dried root and rhizome are used in herbal medicine.

**Goldenseal has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Canker sores</b> (page 90) <b>Chronic candidiasis</b> (page 109) <b>Cold sores</b> (page 119) <b>Common cold/sore throat</b> (page 129) <b>Conjunctivitis/blepharitis</b> (page 136) <b>Diarrhea</b> (page 163) (berberine) <b>Gastritis</b> (page 195) <b>Indigestion</b> (page 260) <b>Infection</b> (page 265) <b>Influenza</b> (page 269) <b>Pap smear (abnormal)</b> (page 3) <b>Parasites</b> (page 343) <b>Urinary tract infection</b> (page 436) <b>Vaginitis</b> (page 438)

### Historical or traditional use (may or may not be supported by scientific studies)

Goldenseal was used by Native Americans as a treatment for irritations and inflammation of the mucous membranes of the respiratory, digestive, and urinary tracts. It was commonly used topically for skin and eye infections and has been used historically as a mouthwash to help heal **canker sores** (page 90). Because of

its anti-microbial activity, goldenseal has a long history of use for infectious **diarrhea** (page 163), upper respiratory tract infections, and vaginal infections. Goldenseal is often recommended by herbalists in combination with **echinacea** (page 669) for the treatment of **colds** (page 129) and **flu** (page 269). Its benefits are most likely limited to helping ease the discomfort of a **sore throat** (page 129) associated with these conditions. Goldenseal was considered a critical remedy for stomach and intestinal problems of all kinds by early 20th century Eclectic physicians (doctors who recommended herbs).<sup>1</sup>

### Active constituents

Little research has been done on whole goldenseal root or rhizome, but many studies have evaluated the properties of its two primary alkaloids, berberine and hydrastine. Berberine, the more extensively researched of the two, accounts for 0.5–6.0% of the alkaloids present in goldenseal root and rhizome. However, the effect of goldenseal in the gastrointestinal tract is most likely localized as its alkaloids (particularly berberine) are poorly absorbed into the bloodstream, limiting any systemic antibiotic effects.<sup>2</sup> Goldenseal also has strong astringent properties which may partially explain its historical use for **sore throats** (page 129) and **diarrhea** (page 163). In test tube studies, it has shown a wide spectrum of antibiotic activity against disease-causing organisms, such as *Chlamydia*, *E. coli*, *Salmonella typhi*, and *Entamoeba histolytica*.<sup>3</sup> Human trials have used isolated berberine to treat diarrhea and gastroenteritis with good results.<sup>4</sup> The whole root has not been clinically studied.

### How much is usually taken?

Powdered goldenseal root and rhizome, 4–6 grams per day in tablet or capsule form, is sometimes recommended.<sup>5</sup> For liquid herbal extracts, use 2–4 ml three times per day. Alternatively, 250–500 mg three times per day of standardized extracts supplying 8–12% alkaloids, are suggested. Continuous use should not exceed three weeks, with a break of at least two weeks between each use.

Due to environmental concerns of overharvesting,<sup>6</sup> many herbalists recommend alternatives to goldenseal, such as **Oregon grape** (page 721) or goldthread.

### Are there any side effects or interactions?

Taken as recommended, goldenseal is generally safe. However, as with all alkaloid-containing plants, high

amounts (several times higher than the recommended amount above) may lead to gastrointestinal distress and possible nervous system effects.<sup>7</sup> Goldenseal is not recommended for **pregnant** (page 363) or breast-feeding women. Also, despite some traditional reports, goldenseal is not a substitute for antibiotics.

## GOTU KOLA

**Botanical name:** *Centella asiatica*

### Parts used and where grown

This plant grows in a widespread distribution in tropical, swampy areas, including parts of India, Pakistan, Sri Lanka, Madagascar, and South Africa. It also grows in Eastern Europe. The roots and leaves are used medicinally.

**Gotu kola has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Chronic venous insufficiency</b> (page 116) <b>Skin ulcers</b> (page 409) (topical and by intramuscular injection) <b>Wound healing</b> (page 319)
★★☆	<b>Burns (minor)</b> (page 85) Scars Scleroderma <b>Varicose veins</b> (page 440)

### Historical or traditional use (may or may not be supported by scientific studies)

Gotu kola has been important in the medicinal systems of central Asia for centuries. In Sri Lanka, it was purported to prolong life, as the leaves are commonly eaten by elephants. Numerous skin diseases, ranging from poorly healing wounds to leprosy, have been treated with gotu kola. Gotu kola also has a historical reputation for boosting mental activity and for helping a variety of illnesses, such as **high blood pressure** (page 246), rheumatism, fever, and nervous disorders. Some of its common applications in Ayurvedic medicine include **heart disease** (page 98), **water retention** (page 180), hoarseness, **bronchitis** (page 80), and **coughs**

(page 139) in children, and as a poultice for many skin conditions.<sup>1</sup>

### Active constituents

The primary active constituents of gotu kola are saponins (also called triterpenoids), which include asiaticoside, madecassoside and madasiatic acid.<sup>2</sup> These saponins may prevent excessive scar formation by inhibiting the production of collagen (the material that makes up connective tissue) at the wound site. These constituents are also associated with promoting wound healing. One preliminary trial in humans found that a gotu kola extract improved healing of infected wounds (unless the infection had reached bone).<sup>3</sup> Additionally, a review of French studies suggests that topical gotu kola can improve healing of **burns** (page 85) and **wounds** (page 319).<sup>4</sup> Clinical trials have also shown it can help those with **chronic venous insufficiency** (page 116)<sup>5, 6</sup> Another trial found gotu kola extract helpful for preventing and treating enlarged scars (keloids).<sup>7</sup>

### How much is usually taken?

Dried gotu kola leaf can be made into a tea by adding 1–2 teaspoons (5–10 grams) to about  $\frac{1}{2}$  cup (150 ml) of boiling water and allowing it to steep for ten to fifteen minutes. Three cups (750 ml) are usually suggested per day. Fluid extract ( $\frac{1}{2}$ –1 teaspoon (3–5 ml) per day) or a tincture (2–4 teaspoons (10–20 ml) per day) are sometimes recommended. Standardized extracts containing up to 100% total saponins (triterpenoids), 60 mg once or twice per day, are frequently used in modern herbal medicine.<sup>8</sup>

### Are there any side effects or interactions?

Except for the rare person who is allergic to gotu kola, no significant adverse effects are experienced with internal or topical use of this herb.<sup>9</sup>

## GREATER CELANDINE

**Botanical name:** *Chelidonium majus*

### Parts used and where grown

Greater celandine grows primarily in Europe and Asia, although it has been introduced in North America. The leaves and small yellow flowers of greater celandine are

used as medicine. Although the roots and rhizomes of the plant have also been used medicinally, most clinical trials have used the above-ground parts of the plant collected at the time of flowering.<sup>1</sup>

**Greater celandine has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Indigestion</b> (page 260)
★★☆	Biliary dyskinesia Cholecystitis <b>Warts</b> (page 445)

**Historical or traditional use (may or may not be supported by scientific studies)**

European herbal traditions regard greater celandine as a valuable remedy for the topical treatment of **warts** (page 445).<sup>2</sup> It was also a folk remedy for **cancer** (page 87), **gout** (page 208), jaundice, and a variety of skin diseases. The famous French herbalist Maurice Mességué used greater celandine extensively in hand and foot baths and teas for many conditions, particularly those affecting the liver.<sup>3</sup> In eastern Asia it was also valued as a treatment for **peptic ulcer** (page 349).<sup>4</sup>

**Active constituents**

Greater celandine, like other members of the Papaveraceae (poppy) family, contains alkaloids as its major constituents. These include chelidoxanthine, chelidoneine, and coptisine. Greater celandine extracts have been shown to stimulate production of bile and pancreatic digestive enzymes in human studies.<sup>5</sup>

Animal and test tube studies have shown that the alkaloids and whole plant extract can relieve gallbladder spasms and stimulate an under-active gallbladder.<sup>6, 7</sup> Test tube and animal studies have also shown celandine extracts and purified alkaloids to have anti-inflammatory, anti-cancer and antimicrobial properties.<sup>8, 9, 10</sup> They have also shown greater celandine's ability to protect animal livers from toxic substances.<sup>11, 12</sup>

A double-blind trial found that a standardized extract of greater celandine could relieve symptoms of **indigestion** (page 260) (such as abdominal cramping, sensation of fullness, and nausea) significantly better than a placebo.<sup>13</sup> The trial used an extract standardized

to 4 mg of chelidonine per capsule and gave 1–2 tablets three times daily for six weeks. An earlier, preliminary trial also found the same extract reduced symptoms in people with indigestion.<sup>14</sup>

Preliminary reports from Russia and China have reported that a tincture of greater celandine applied topically was useful for **warts** (page 445).<sup>15</sup> However, these results have not yet been confirmed by double-blind clinical trials.

Several reports describe Eastern European clinical trials using semi-synthetic derivatives of greater celandine alkaloids for people with **cancer** (page 87).<sup>16</sup> This injectable product goes by the name Ukrain. The findings on this drug cannot be applied to greater celandine because the alkaloids have been modified from their original form.

**How much is usually taken?**

One explanation for the variable results obtained from using greater celandine is improperly prepared, dried extracts.<sup>17</sup> Drying extracts quickly at high temperature is necessary to preserve the alkaloids.<sup>18</sup> Extracts standardized to a content of 4 mg chelidonine per capsule are recommended to be taken three times per day.<sup>19</sup> Alternatively, one may mix 1–3 ml tincture into water and sip slowly 10–30 minutes before eating. Topical applications should consist of either concentrated tinctures or the fresh yellow latex. Herbalists and doctors recommend applying fresh latex once per day to warts and allowing it to dry in place.<sup>20</sup>

**Are there any side effects or interactions?**

Use of fresh plant products may cause stomach upset.<sup>21</sup> Topical use has been associated with intense itching and a rash in one case.<sup>22</sup> Greater celandine should be avoided during **pregnancy** (page 363) and in children under age 12.<sup>23</sup> A recent report of ten women in Germany suffering from acute **hepatitis** (page 220) following supplementation with a standardized extract of greater celandine (dosage was not given) suggest this herb should be avoided by people with hepatitis or impaired liver function. Greater celandine should be used cautiously and under the supervision of a healthcare professional until more is understood about its potential liver toxicity.<sup>24</sup>

**Special United Kingdom considerations**

Greater celandine is available only by prescription in the United Kingdom.

## GREEN TEA

**Common name:** Epigallocatechin gallate (EGCG)

**Botanical name:** *Camellia sinensis*

### Parts used and where grown

All teas (green, black, and oolong) are derived from the same plant, *Camellia sinensis*. The difference is in how the plucked leaves are prepared. Green tea, unlike black and oolong tea, is not fermented, so the active constituents remain unaltered in the herb. The leaves of the tea plant are used both as a social and a medicinal beverage.

**Green tea has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Atherosclerosis</b> (page 38) <b>Cervical dysplasia</b> (page 3) (poly E or (-)-epigallocatechin-3-gallate) <b>Colon cancer</b> (page 123) (reduces risk) <b>High cholesterol</b> (page 223) <b>Leukoplakia</b> (page 289) <b>Tooth decay</b> (page 430) <b>Weight loss</b> (page 446)
★★★	<b>Breast cancer</b> (page 65) (risk reduction) <b>Crohn's disease</b> (page 141) <b>Hemochromatosis</b> (iron overload) <b>High triglycerides</b> (page 235) <b>Hives</b> (page 246) <b>Immune function</b> (page 255) <b>Infection</b> (page 265) <b>Lung cancer</b> (page 298) (risk reduction)

### Historical or traditional use (may or may not be supported by scientific studies)

According to Chinese legend, tea was discovered accidentally by an emperor 4,000 years ago. Since then, Traditional Chinese Medicine has recommended green tea for headaches, body **aches and pains** (page 338), digestion, **depression** (page 145), **immune enhancement** (page 255), detoxification, as an energizer, and to prolong life.

### Active constituents

Green tea contains volatile oils, vitamins, minerals, and caffeine, but the primary constituents of interest are the polyphenols, particularly the catechin called epigallo-

catechin gallate (EGCG). The polyphenols are believed to be responsible for most of green tea's roles in promoting good health.<sup>1</sup>

Green tea has been shown to mildly lower total **cholesterol** (page 223) levels and improve the cholesterol profile (decreasing LDL "bad" cholesterol and increasing HDL "good" cholesterol) in most,<sup>2, 3, 4, 5</sup> but not all,<sup>6</sup> studies. Green tea may also promote **cardiovascular health** (page 98) by making platelets in the blood less sticky.

Green tea has also been shown to protect against damage to LDL ("bad") cholesterol caused by oxygen.<sup>7</sup> Consumption of green tea increases antioxidant activity in the blood.<sup>8</sup> Oxidative damage to LDL can promote **atherosclerosis** (page 38). While population studies have suggested that consumption of green tea is associated with protection against atherosclerosis,<sup>9</sup> the evidence is still preliminary.

Several animal and test tube studies have demonstrated an anticancer effect of polyphenols from green tea.<sup>10, 11, 12</sup> In one of these studies, a polyphenol called catechin from green tea effectively inhibited metastasis (uncontrolled spread) of melanoma (skin cancer) cells.<sup>13</sup> The polyphenols in green tea have also been associated with reduced risk of several types of **cancer** (page 87) in humans.<sup>14, 15, 16</sup> However, some human studies have found no association between green tea consumption and decreased cancer risk.<sup>17, 18</sup>

In a double-blind trial, people with **leukoplakia** (page 289) (a pre-cancerous oral condition) took 3 grams orally per day of a mixture of whole green tea, green tea polyphenols, and green tea pigments orally, and also painted a mixture of the tea on their lesions three times daily for six months.<sup>19</sup> As compared to the placebo group, those in the green tea group had significant decreases in the pre-cancerous condition.

Compounds in green tea, as well as black tea, may reduce the risk of dental caries.<sup>20</sup> Human volunteers rinsing with an alcohol extract of oolong tea leaves before bed each night for four days had significantly less plaque formation, but similar amounts of plaque-causing bacteria, compared to those with no treatment.<sup>21</sup>

Green tea polyphenols have been shown to stimulate the production of several **immune system** (page 255) cells, and have topical antibacterial properties—even against the bacteria that cause dental plaque.<sup>22, 23, 24</sup>

One study found that intake of 10 cups or more of green tea per day improved blood test results, indicating protection against liver damage.<sup>25</sup> Further studies

are needed to determine if taking green tea helps those with liver diseases.

Tea **flavonoids** (page 516) given by capsule reduced fecal odor and favorably altered the gut bacteria in elderly Japanese with feeding tubes living in nursing homes.<sup>26</sup> The study was repeated in bedridden elderly not on feeding tubes, and green tea was again shown to improve their gut bacteria.<sup>27</sup> These studies raise the possibility of using green tea in other settings where gut bacteria are disturbed, such as after taking antibiotics. Further studies are needed to clarify the role of green tea in this respect, however.

High-tannin tea has been shown to reduce the need for blood removal from people with iron overload, or hemochromatosis, in an open study.<sup>28</sup> The tea had to be taken with meals and without lemon or milk to be effective. Tea is believed to help in hemochromatosis by preventing iron absorption.

#### **How much is usually taken?**

Much of the research documenting the health benefits of green tea is based on the amount of green tea typically consumed in Asian countries—about 3 cups (750 ml) per day (providing 240–320 mg of polyphenols).<sup>29</sup> However, other research suggests as much as 10 cups (2,500 ml) per day is necessary to obtain noticeable benefits from green tea ingestion.<sup>30, 31</sup> To brew green tea, 1 teaspoon (5 grams) of green tea leaves are combined with 1 cup (250 ml) of boiling water and steeped for three minutes. Decaffeinated tea is recommended to reduce the side effects associated with caffeine, including **anxiety** (page 30) and **insomnia** (page 270). Tablets and capsules containing standardized extracts of polyphenols, particularly EGCG, are available. Some provide up to 97% polyphenol content—which is equivalent to drinking 4 cups (1,000 ml) of tea. Many of these standardized products are decaffeinated.

#### **Are there any side effects or interactions?**

Green tea is generally free of side effects. The most common adverse effects reported from consuming large amounts (several cups per day) of green tea are **insomnia** (page 270), **anxiety** (page 30), and other symptoms caused by the caffeine content in the herb.

An extract of green tea taken by healthy women with a meal inhibited the absorption of non-heme iron (e.g., the form of iron in plant foods) by 26%.<sup>32</sup> Frequent use of green tea could, in theory, promote the development of iron deficiency in susceptible individuals.

## GUARANÁ

**Botanical name:** *Paullinia cupana*

#### **Parts used and where grown**

Guaraná is an evergreen vine indigenous to the Amazon basin. The vast majority of guaraná is grown in a small area in northern Brazil. Guaraná gum or paste is derived from the seeds and is used in herbal preparations.

**Guaraná has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Athletic performance</b> (page 43)
	Fatigue
	<b>Weight loss and obesity</b> (page 446)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

The indigenous people of the Amazon rain forest have used crushed guaraná seed as a beverage and a medicine. Guaraná was used to treat **diarrhea** (page 163), decrease fatigue, reduce hunger, and to help arthritis.<sup>1</sup> It also has a history of use in treating hangovers from alcohol abuse and headaches related to menstruation.

#### **Active constituents**

Caffeine and the closely related alkaloids theobromine and theophylline make up the primary active constituents in guaraná. Caffeine's effects are well known and include stimulating the central nervous system, increasing metabolic rate, and having a mild diuretic effect.<sup>2</sup> One preliminary trial found no significant actions on thinking or mental function in humans taking guaraná.<sup>3</sup> Guaraná also contains tannins, which act as astringents and may prevent **diarrhea** (page 163). However, this action has not been studied in human clinical trials.

#### **How much is usually taken?**

A cup of guaraná, prepared by adding  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–2 grams) of crushed seed or resin to 1 cup (250 ml) of water and boiling for ten minutes, can be consumed three times per day.<sup>4</sup> Each cup may provide up to 50 mg of caffeine.

### Are there any side effects or interactions?

As with any caffeinated product, guaraná may cause **insomnia** (page 270), trembling, **anxiety** (page 30), palpitations, and urinary frequency.<sup>5</sup> Guaraná should be avoided during **pregnancy** (page 363) and breastfeeding.

## GUGGUL

**Common names:** Guglipid, gum guggulu

**Botanical name:** *Commiphora mukul*

### Parts used and where grown

The mukul myrrh (*Commiphora mukul*) tree is a small, thorny plant distributed throughout India. Guggul and gum guggulu are the names given to a yellowish resin produced by the stem of the plant. This resin has been used historically and is also the source of modern extracts of guggul.

**Guggul has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>High triglycerides</b> (page 235)
★★☆	<b>Acne vulgaris</b> (page 6) <b>Atherosclerosis</b> (page 38) <b>High cholesterol</b> (page 223) <b>Osteoarthritis</b> (page 328)
★☆☆	<b>Obesity</b> (page 446)

### Historical or traditional use (may or may not be supported by scientific studies)

The classical treatise on Ayurvedic medicine, *Sushrita Samhita*, describes the use of guggul for a wide variety of conditions, including rheumatism and **obesity** (page 446). One of its primary indications was a condition known as *medoroga*. This ancient diagnosis is similar to the modern description of **atherosclerosis** (page 38). Standardized guggul extracts are approved in India for lowering elevated serum **cholesterol** (page 223) and **triglyceride** (page 235) levels.

### Active constituents

Guggul contains resin, volatile oils, and gum. The extract isolates ketonic steroid compounds known as guggulsterones.

These compounds have been shown to provide the cholesterol- and triglyceride-lowering actions noted for guggul.<sup>1</sup> Guggul significantly lowers serum **triglycerides** (page 235) and **cholesterol** (page 223) as well as LDL and VLDL cholesterol (the “bad” cholesterol).<sup>2</sup> At the same time, it raises levels of HDL cholesterol (the “good” cholesterol). As **antioxidants** (page 467), guggulsterones keep LDL cholesterol from oxidizing, an action which protects against **atherosclerosis** (page 38).<sup>3</sup> Guggul has also been shown to reduce the stickiness of platelets—another effect that lowers the risk of coronary artery disease.<sup>4</sup> One double-blind trial found guggul extract similar to the drug clofibrate for lowering cholesterol levels.<sup>5</sup> Other clinical trials in India (using 1,500 mg of extract per day) have confirmed guggul extracts improve lipid levels in humans.<sup>6</sup>

A combination of guggul, phosphate salts, hydroxycitrate, and **tyrosine** (page 544) coupled with exercise has been shown in a double-blind trial to improve mood with a slight tendency to improve weight loss in overweight adults.<sup>7</sup>

One small clinical trial found that guggul (*Commiphora mukul*) compared favorably to tetracycline in the treatment of cystic acne.<sup>8</sup> The amount of guggul extract taken in the trial was 500 mg twice per day.

### How much is usually taken?

Daily recommendations for the purified guggul extract are typically based on the amount of guggulsterones in the extract.<sup>9</sup> A common intake of guggulsterones is 25 mg three times per day. Most extracts contain 2.5–5% guggulsterones and can be taken daily for 12 to 24 weeks for lowering **high cholesterol** (page 223) and/or **triglycerides** (page 235).

### Are there any side effects or interactions?

Early studies with the crude oleoresin reported numerous side effects, including **diarrhea** (page 163), **anorexia** (page 174), abdominal pain, and skin rash. Modern extracts are more purified, and fewer side effects (e.g., mild abdominal discomfort) have been reported with long-term use. Rash was reported, however, as a fairly common side effect in one recent study.<sup>10</sup> Guggul should be used with caution by people with liver disease and in cases of **inflammatory bowel disease** (page 269) and **diarrhea** (page 163). A physician should be consulted before treating elevated **cholesterol** (page 223) and **triglycerides** (page 235).

## GYMNEMA

**Common names:** Gurmarbooti, gurmar

**Botanical name:** *Gymnema sylvestre*

### Parts used and where grown

*Gymnema sylvestre* is a woody climbing plant that grows in the tropical forests of central and southern India. The leaves are used in herbal medicine preparations. *G. sylvestre* is known as “periploca of the woods” in English and *meshasringi* (meaning “ram’s horn”) in Sanskrit. The leaves, when chewed, interfere with the ability to taste sweetness, which explains the Hindi name *gurmar*—“destroyer of sugar.”

**Gymnema has been used in connection with the following condition** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Diabetes</b> (page 152)

### Historical or traditional use (may or may not be supported by scientific studies)

Gymnema has been used in India for the treatment of **diabetes** (page 152) for over 2,000 years. The leaves were also used for stomach ailments, **constipation** (page 137), **water retention** (page 180), and liver disease.

### Active constituents

The hypoglycemic (blood sugar-lowering) action of gymnema leaves was first documented in the late 1920s.<sup>1</sup> This action is attributed to members of a family of substances called gymnemic acids.<sup>2, 3</sup> Gymnema leaves raise insulin levels, according to research in healthy volunteers.<sup>4</sup> Based on animal studies, this may be due to regeneration of the cells in the pancreas that secrete insulin,<sup>5, 6</sup> or by increasing the flow of insulin from these cells.<sup>7</sup> Other animal research shows that gymnema can also reduce glucose absorption from the intestine,<sup>8</sup> improve uptake of glucose into cells, and prevent adrenal hormones from stimulating the liver to produce glucose, thereby reducing blood sugar levels.<sup>9, 10</sup>

Other animal studies have shown that extracts of gymnema leaves can lower serum **cholesterol** (page 223) and **triglycerides** (page 235) and prevent weight gain,<sup>11, 12, 13, 14</sup> but these effects have not been tested in humans. When placed directly on the tongue, gur-

marin, another constituent of the leaves, and gymnemic acid have been shown to block the ability in humans to taste sweets.<sup>15, 16</sup>

### How much is usually taken?

Clinical trials with diabetics in India have used 400 mg per day of a water-soluble acidic fraction of the gymnema leaves. The gymnemic acid content of this extract is not clear. A recent preliminary trial in the United States reported promising results in a group of type 1 and type 2 diabetics who took 800 mg per day of an extract standardized for 25% gymnemic acids.<sup>17</sup> Traditionally, 2 to 4 grams per day of the leaf powder is used.

### Are there any side effects or interactions?

Used at the amounts suggested, gymnema is generally safe and devoid of side effects. The safety of gymnema during **pregnancy** (page 363) and breast-feeding has not yet been determined. People with **diabetes** (page 152) should only use gymnema to lower blood sugar under the clinical supervision of a healthcare professional. Gymnema cannot be used in place of insulin to control blood sugar by people with either type 1 or type 2 diabetes.

## HAWTHORN

**Botanical names:** *Crataegus laevigata*, *Crataegus oxyacantha*, *Crataegus monogyna*

### Parts used and where grown

Hawthorn is commonly found in Europe, western Asia, North America, and North Africa. Modern medicinal extracts primarily use the leaves and flowers. Traditional preparations use the fruit.

**Hawthorn has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Congestive heart failure</b> (page 134) (early-stage)
★★☆	<b>Angina</b> (page 27) <b>Cardiomyopathy</b> (page 95) (if <b>congestive heart failure</b> [page 134] is also present)
★☆☆	<b>Cardiac arrhythmia</b> (page 93) <b>Cardiomyopathy</b> (page 95) (if <b>congestive heart failure</b> [page 134] is not present) <b>Hypertension</b> (page 246)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Dioscorides, a Greek herbalist, reportedly used hawthorn in the first century A.D. Although numerous passing mentions are made for a variety of conditions, support for the heart is the main benefit of hawthorn.

### **Active constituents**

The leaves, flowers, and berries of hawthorn contain a variety of bioflavonoids that appear to be primarily responsible for the cardiac actions of the plant. **Flavonoids** (page 516) found in hawthorn include **oligomeric procyanidins** (page 574) (OPCs), vitexin, vitexin 4'-O-rhamnoside, **quercetin** (page 580), and hyperoside. These compounds are often standardized in leaf and flower extracts, which are widely used in Europe.

Hawthorn is thought to exert many beneficial effects on the heart and blood vessels. These include improved coronary artery blood flow and strengthening of the contractions of the heart muscle.<sup>1</sup> Hawthorn may also improve circulation to the extremities by lowering the resistance to blood flow in peripheral blood vessels.<sup>2</sup> The bioflavonoids in hawthorn are potent **antioxidants** (page 467).<sup>3</sup> Hawthorn extracts may mildly lower blood pressure in some people with **high blood pressure** (page 246) but should not be thought of as a substitute for cardiac medications for this condition.

Clinical trials have confirmed that hawthorn leaf and flower extracts are beneficial for people with stage II (early-stage) **congestive heart failure** (page 134).<sup>4, 5, 6, 7, 8</sup> People with congestive heart failure taking 160–900 mg of hawthorn extract per day for eight weeks showed improved quality of life including greater ability to exercise without shortness of breath and exhaustion. Congestive heart failure is a serious medical condition that requires expert management rather than self-treatment. One study has shown that hawthorn leaf and flower extract may also help those with stable **angina** (page 27).<sup>9</sup>

### **How much is usually taken?**

Extracts of the leaves and flowers are most commonly used in modern herbal medicine. Hawthorn extracts standardized for total bioflavonoid content (usually 2.2%) or **oligomeric procyanidins** (page 574) (usually 18.75%) are often suggested. Many doctors recommend 80–300 mg of the herbal extract in capsules or tablets two to three times per day.<sup>10</sup> If traditional berry

preparations are used, the recommendation is at least 4–5 grams per day or a tincture of 4–5 ml three times daily. However, this form has not been clinically studied. Hawthorn is slow acting and may take one to two months for maximum effects to be seen. However, it appears to be safe and should be considered a long-term therapy.

### **Are there any side effects or interactions?**

Hawthorn is safe for long-term use. People taking prescription cardiac medications should consult with their doctor before using hawthorn-containing products. Reports of hawthorn interacting with digitalis to augment its effects have not been confirmed in clinical trials. There are no apparent restrictions to use of hawthorn during **pregnancy** (page 363) or breast-feeding.

## **HOPS**

**Botanical name:** *Humulus lupulus*

### **Parts used and where grown**

The hops plant, *Humulus lupulus*, is a climbing plant native to Europe, Asia, and North America. Hops are the cone-like, fruiting bodies (strobiles) of the plant and are typically harvested from cultivated female plants. Hops are most commonly used as a flavoring agent in beer.

**Hops have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Anxiety</b> (page 30) <b>Insomnia</b> (page 270) Poor appetite

### **Historical or traditional use (may or may not be supported by scientific studies)**

Soothing the stomach and promoting healthy digestion have been the strongest historical use of this herb. Hops tea was also recommended by herbalists as a mild sedative and remedy for **insomnia** (page 270), particularly for those with insomnia resulting from an upset stomach.<sup>1</sup> A pillow filled with hops was sometimes used to

encourage sleep. Traditionally, hops were also thought by herbalists to have a diuretic effect and to treat sexual neuroses. A poultice of hops was used topically to treat sores and skin injuries and to relieve muscle spasms and nerve pain.<sup>2</sup>

#### Active constituents

Hops are high in bitter substances. The two primary bitter constituents are known as humulone and lupulone.<sup>3</sup> These are thought to be responsible for the appetite-stimulating properties of hops. Hops also contain about 1–3% volatile oils. Hops have been shown to have mild sedative properties, although the mechanism is unclear.<sup>4</sup> Some herbal preparations for insomnia combine hops with more potent sedative herbs, such as **valerian** (page 756). Hops also contain phytoestrogens that bind estrogen receptors in test tube studies but are thought to have only mild estrogen-like actions.<sup>5</sup>

#### How much is usually taken?

The German Commission E monograph recommends a single application of 500 mg of dried herb for **anxiety** (page 30) or **insomnia** (page 270).<sup>6</sup> The dried fruits can be made into a tea by pouring 1 cup (250 ml) of boiling water over 1–2 teaspoons (5–10 grams) of the fruit. Steep for ten to fifteen minutes before drinking. Tinctures,  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–2 ml) two or three times per day, can also be used. As mentioned above, many herbal preparations use hops in combination with herbal sedatives, including **valerian** (page 756), **passion flower** (page 722), and scullcap.

#### Are there any side effects or interactions?

Use of hops is generally safe. However, some people have been reported to experience an allergic skin rash after handling the dried flowers. This is most likely due to a pollen sensitivity.<sup>7</sup>

## HOREHOUND

**Botanical name:** *Marrubium vulgare*

#### Parts used and where grown

Horehound is a perennial plant with small white flowers found growing in the wild throughout Europe and Asia. All parts of the plant are used medicinally.<sup>1</sup>

**Horehound has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Bronchitis</b> (page 80) <b>Cough</b> (page 139) <b>Indigestion</b> (page 260) Lack of appetite

#### Historical or traditional use (may or may not be supported by scientific studies)

Horehound was reportedly first used in ancient Rome by the physician Galen, who recommended it as a therapy for coughs and other respiratory ailments. Like Galen, Nicholas Culpeper, the 17th-century English pharmacist, commented that it was helpful for a **cough** (page 139) and was also useful in helping remove stubborn phlegm from the lung. Similarly, American Eclectic physicians (doctors who recommended herbs) of the 19th century remarked on its value as a medicinal plant not only for coughs and **asthma** (page 32) but also in menstrual complaints.<sup>2</sup>

#### Active constituents

Horehound contains a number of constituents, including alkaloids, **flavonoids** (page 516), diterpenes (e.g., marrubiin), and trace amount of volatile oils.<sup>3</sup> The major active constituent in horehound is marrubiin, which is thought to be responsible for the expectorant (promotion of coughing up of mucus) action of the herb. In addition, marrubiin contributes to the bitter taste of horehound, an action that increases the flow of saliva and gastric juice, thereby stimulating the appetite.<sup>4</sup> These actions likely explain the long-standing use of horehound as a cough suppressant and expectorant as well as a bitter digestive tonic.

#### How much is usually taken?

For adults, the German Commission E monograph recommends approximately  $\frac{3}{4}$  teaspoon (4.5 grams) of horehound per day or 2–6 tablespoons (30–90 ml) of the pressed juice.<sup>5</sup> Alternatively, horehound tea can be prepared from approximately  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–2 grams) of root boiled in about 7 ounces (200 ml) of water for ten minutes. Three cups (750 ml) of this tea can be drunk per day. Horehound is sometimes found in herbal lozenges that are used for coughs.

### Are there any side effects or interactions?

Since horehound acts as a bitter and may increase production of stomach acid, people with gastritis or **peptic ulcer** (page 349) disease should use it cautiously. Horehound should not be used during **pregnancy** (page 363), as it may stimulate contractions.

## HORSE CHESTNUT

**Botanical name:** *Aesculus hippocastanum*

### Parts used and where grown

The horse chestnut tree is native to Asia and northern Greece, but it is now cultivated in many areas of Europe and North America. The tree produces fruits that are made up of a spiny capsule containing one to three large seeds, known as horse chestnuts. Traditionally, many of the aerial parts of the horse chestnut tree, including the seeds, leaves, and bark, were used in medicinal preparations. Modern extracts of horse chestnut are usually made from the seeds, which are high in the active constituent aescin (also known as escin).

**Horse chestnut has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Chronic venous insufficiency</b> (page 116)
★★☆	<b>Hemorrhoids</b> (page 219) <b>Sprains and strains</b> (page 412) (topical) <b>Wound healing</b> (page 319) (topical)
★☆☆	<b>Edema (water retention)</b> (page 180) <b>Varicose veins</b> (page 440)

### Historical or traditional use (may or may not be supported by scientific studies)

Horse chestnut leaves have been used by herbalists as a **cough** (page 139) remedy and to reduce fevers.<sup>1</sup> The leaves were also believed to reduce pain and inflammation of arthritis and rheumatism. In traditional herbal medicine, poultices of the seeds have been used topically to treat skin ulcers and skin **cancer** (page 87). Other uses include the internal and external application for problems of venous circulation, including **varicose veins** (page 440) and **hemorrhoids** (page 219).

### Active constituents

The seeds are the source of a saponin known as aescin, which has been shown to promote circulation through the veins.<sup>2</sup> Aescin fosters normal tone in the walls of the veins, thereby promoting return of blood to the heart. This has made both topical and internal horse chestnut extracts popular in Europe for the treatment of **chronic venous insufficiency** (page 116) and, to a lesser extent, **varicose veins** (page 440). Aescin also possesses anti-inflammatory properties and has been shown to reduce **edema** (page 180) (swelling with fluid) following trauma, particularly following sports injury, surgery, and head injury.<sup>3, 4</sup> A topical aescin preparation is very popular in Europe for the treatment of acute sprains during sporting events. Horse chestnuts also contain **flavonoids** (page 516), sterols, and tannins.

Double-blind and preliminary clinical trials have shown that oral horse chestnut extracts reduce the symptoms of **chronic venous insufficiency** (page 116), including swelling and pain.<sup>5, 6</sup> Those suffering edema after surgery have also found relief from topical application of horse chestnut extracts, according to preliminary studies.<sup>7</sup>

### How much is usually taken?

For treatment of **chronic venous insufficiency** (page 116) horse chestnut seed extracts standardized for aescin content (16–20%), 300 mg two to three times per day, are recommended.<sup>8, 9</sup> Tincture, 1–4 ml taken three times per day, can be used though it is questionable whether a significant amount of aescin can be absorbed this way.<sup>10</sup> Gels or creams containing 2% aescin can be applied topically three or four times per day for **hemorrhoids** (page 219), skin ulcers, **varicose veins** (page 440), sports injuries, and trauma of other kinds.

### Are there any side effects or interactions?

Internal use of horse chestnut seed extracts standardized for aescin at recommended amounts is generally safe. However, in rare cases oral intake of horse chestnut may cause itching, nausea, and upset stomach.<sup>11</sup> Based on reports of worsening kidney function in people with kidney disease who received intravenous aescin, horse chestnut should be avoided by anyone with kidney disease.<sup>12, 13</sup> People with liver disease should also avoid the use of horse chestnut. There are no known reasons to avoid horse chestnut during **pregnancy** (page 363).<sup>14</sup> Topically, horse chestnut has been associated with rare cases of allergic skin reactions. Circulation disorders and trauma associated with swelling may be the sign of

a serious condition. Therefore, a healthcare professional should be consulted before self-treating with horse chestnut.

## HORSERADISH

**Botanical name:** *Cochlearia armoracia*

### Parts used and where grown

Horseradish likely originated in Eastern Europe, but today it is cultivated worldwide. The root is used as both food and medicine.

**Horseradish has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Bronchitis</b> (page 80) <b>Common cold/sore throat</b> (page 129) <b>Sinusitis</b> (page 407) <b>Urinary tract infection</b> (page 436)

### Historical or traditional use (may or may not be supported by scientific studies)

Horseradish, known for its pungent taste, has been used as a medicine and condiment for centuries in Europe. Its name is derived from the common practice of naming a food according to its similarity with another food (horseradish was considered a rough substitute for radishes).

Horseradish was utilized both internally and externally by European herbalists. Applied to the skin, it causes reddening and was used on arthritic joints or irritated nerves. Internally, it was considered to be a diuretic and was used by herbalists to treat **kidney stones** (page 284) or **edema** (page 180). It was also recommended as a digestive stimulant and to treat worms, **coughs** (page 139), and **sore throats** (page 129).<sup>1</sup>

### Active constituents

Horseradish contains volatile oils that are similar to those found in mustard. These include glucosinolates (mustard oil glycosides), gluconasturtiin, and sinigrin, which yield allyl isothiocyanate when broken down in the stomach. In test tubes, the volatile oils in horseradish have shown antibiotic properties, which may ac-

count for its effectiveness in treating throat and upper respiratory tract infections.<sup>2</sup> At levels attainable in human urine after taking the volatile oil of horseradish, the oil has been shown to kill bacteria that can cause **urinary tract infections** (page 436)<sup>3</sup> and one early trial found that horseradish extract may be a useful treatment for people with urinary tract infections.<sup>4</sup> Further studies are still necessary, however, to confirm horseradish's safety and effectiveness in treating urinary tract infections.

### How much is usually taken?

The German Commission E monograph suggests an average daily intake of 4 teaspoons (20 grams) of the fresh root for adults.<sup>5</sup> Alternatively,  $\frac{1}{2}$ –1 teaspoon (3–5 grams) of the freshly grated root can be eaten three times per day. Horseradish tincture is also available and is sometimes taken at  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (2–3 ml) three times daily. The German Commission E also recommends external use of horseradish for respiratory tract congestion as well as minor muscle aches. A poultice can be prepared by grating the fresh root and spreading it on a linen cloth or thin gauze. This is then applied against the skin once or twice per day until a burning sensation is experienced.

### Are there any side effects or interactions?

If used in amounts higher than recommended, horseradish can cause stomach upset,<sup>6</sup> vomiting, or excessive sweating. Direct application to the skin or eyes may cause irritation and burning. Horseradish should be avoided by people with **hypothyroidism** (page 252), **gastritis** (page 195), **peptic ulcer disease** (page 349), and kidney disorders. Horseradish should not be used by women during **pregnancy** (page 363) or breast-feeding or by children under four years of age.<sup>7</sup>

## HORSETAIL

**Common names:** Bottlebrush plant, shave grass, scouring rush

**Botanical name:** *Equisetum arvense*

### Parts used and where grown

Horsetail is widely distributed throughout the temperate climate zones of the Northern Hemisphere, including Asia, North America, and Europe.<sup>1</sup> Horsetail is a unique plant with two distinctive types of stems.

One variety of stem grows early in spring and looks like asparagus, except for its brown color and spore-containing cones on top. The mature form of the herb, appearing in summer, has branched, thin, green, sterile stems and looks like a feathery tail.

**Horsetail has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Brittle nails</b> (page 79)
	<b>Edema (water retention)</b> (page 180)
	<b>Osteoarthritis</b> (page 328)
	<b>Osteoporosis</b> (page 333)
	<b>Urinary tract infection</b> (page 436)
	<b>Wound healing</b> (page 319) (topical)

**Historical or traditional use (may or may not be supported by scientific studies)**

Reportedly first recommended by the Roman physician Galen, several cultures have employed horsetail as a folk remedy for kidney and bladder troubles, arthritis, bleeding ulcers, and tuberculosis. In addition, the topical use of horsetail was used traditionally to stop the bleeding of wounds and promote rapid healing. The use of this herb as an abrasive cleanser to scour pots or shave wood illustrates the origin of horsetail's common names—scouring rush and shave grass.<sup>2</sup>

**Active constituents**

Horsetail is rich in silicic acid and silicates, which provide approximately 2–3% elemental **silicon** (page 586). **Potassium** (page 572), aluminum, and **manganese** (page 553), along with fifteen different types of **flavonoids** (page 516), are also found in this herb. The presence of these flavonoids, as well as saponins, is believed to cause the diuretic effect, while the silicon content is thought to exert a connective tissue-strengthening and anti-arthritis action.<sup>3</sup> Some experts have suggested the element silicon in horsetail is also a vital component for bone and cartilage formation.<sup>4</sup> Anecdotal reports suggest that horsetail may be of some use in the treatment of **brittle nails** (page 79).<sup>5</sup>

**How much is usually taken?**

The German Commission E monograph suggests up to 6 grams of the herb per day for internal use.<sup>6</sup> A tincture can also be used at 2 teaspoons (10 ml) three times per day. A horsetail tea may be made by boiling 2–4 tea-

spoons of the herb in one cup (250 ml) of water for five minutes. Steep the tea for an additional 15 minutes, strain, and drink two or three times daily. The tea can also be used externally as well as internally.

**Are there any side effects or interactions?**

Horsetail is generally considered safe. The only concern would be that the correct species of horsetail is used. *Equisetum palustre* is another species of horsetail, which contains toxic alkaloids and is a well-known livestock poison. Due to a lack of clear safety information, horsetail should be avoided during **pregnancy** (page 363) and breast-feeding.

The Canadian Health Protection Branch requires supplement manufacturers to document that their products do not contain the enzyme thiaminase, found in crude horsetail, which destroys the B vitamin **thiamine** (page 597). Since alcohol, temperature, and alkalinity neutralize this potentially harmful enzyme, tinctures, fluid extracts, or preparations of the herb subjected to 100°C temperatures during manufacturing are preferred for medicinal use.<sup>7</sup>

## HUPERZIA

**Common names:** Qian ceng ta, huperzine A

**Parts used and where grown**

Huperzia is a type of moss that grows in China. It is related to club mosses (the *Lycopodiaceae* family) and is known to some botanists as *Lycopodium serratum*. The whole prepared moss was used traditionally. Modern herbal preparations use only the isolated alkaloid known as huperzine A.

**Huperzia has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Alzheimer's disease</b> (page 19)
	<b>Age-related cognitive decline</b> (page 8)

**Historical or traditional use (may or may not be supported by scientific studies)**

Huperzia moss tea has been used for centuries in traditional Chinese herbalism for fever, as a diuretic, for blood loss, and for irregular menstruation.<sup>1</sup>

### Active constituents

Huperzine A is an alkaloid found in huperzia that has been reported to prevent the breakdown of acetylcholine, an important substance needed by the nervous system to transmit information from cell to cell.<sup>2</sup> Animal research has suggested that huperzine A's ability to preserve acetylcholine may be greater than that of some prescription drugs.<sup>3, 4</sup> Loss of acetylcholine function is a primary feature of several disorders of brain function, including **Alzheimer's disease** (page 19). Huperzine A may also have a protective effect on brain tissue, further increasing its theoretical potential for helping reduce symptoms of some brain disorders.<sup>5, 6</sup>

In a double-blind trial, people with **Alzheimer's disease** (page 19) had significant improvement in memory and cognitive and behavioral functions after taking 200 mcg of huperzine A twice per day for eight weeks.<sup>7</sup> Another double-blind trial using injected huperzine A confirmed a positive effect in people with dementia, including, but not limited to, Alzheimer's disease.<sup>8</sup> Another double-blind trial found that huperzine A (100–150 mcg two to three times per day for four to six weeks) was more effective for improving minor memory loss associated with **age-related cognitive decline** (page 8) than the drug piracetam.<sup>9</sup>

Huperzine A has also been shown to enhance memory in adolescent middle school students. A small controlled trial found that 100 mcg of huperizine A two times per day for four weeks was effective in improving memory and learning performance.<sup>10</sup> Although no side effects were reported in this short trial, long-term safety studies are needed before huperizine A is recommended for adolescents or younger children to improve memory and learning performance.

### How much is usually taken?

Human research on huperzine A has used 100–200 mcg taken two to three times per day.<sup>11</sup>

### Are there any side effects or interactions?

Medications that prevent acetylcholine breakdown often produce side effects, including nausea, vomiting, excess saliva and tear production, and sweating. However, while dizziness was reported in a few people in one study, no severe side effects have been reported in human trials using huperzine A. Further studies are needed to determine the long-term safety of huperzine A.

## HYSSOP

**Botanical name:** *Hyssopus officinalis*

### Parts used and where grown

Hyssop reportedly originated in the area around the Black Sea in central Asia and today is widely cultivated in other arid regions, partly because it thrives even in the most desolate soils. Hyssop's fragrant flowers and leaves are used as medicine.

**Hyssop has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Asthma</b> (page 32) <b>Colic</b> (page 121) <b>Common cold</b> (page 129)/pharyngitis <b>Cough</b> (page 139)

### Historical or traditional use (may or may not be supported by scientific studies)

The most common uses of hyssop in traditional herbalism have been to relieve chest congestion and **coughs** (page 139), to soothe **sore throats** (page 129), and to act as a mild sedative.<sup>1</sup> Some herbalists consider it stronger for relieving gas or intestinal cramping than for easing a cough.<sup>2</sup> In addition to using hyssop for the above conditions, early 20th century Eclectic physicians (doctors who recommended herbs) in the United States used the herb topically to soothe burned skin.<sup>3</sup>

### Active constituents

Due to the presence of volatile oil constituents in hyssop, it may provide relief for mild irritations of the upper respiratory tract that accompany the **common cold** (page 129). The expectorant action of hyssop's volatile oil may partially explain its traditional use for **coughs** (page 139), **asthma** (page 32), and **bronchitis** (page 80).<sup>4</sup> The volatile oils are also thought to contribute to hyssop's carminative actions and use for mild cramping and discomfort in the digestive tract. The German Commission E has not approved hyssop for any medical indication.<sup>5</sup> Test tube studies have found that certain fractions of hyssop (one being a polysaccharide designated as MAR-10) may inhibit the activity of the **human immunodeficiency virus** (page 239).

(HIV).<sup>6,7</sup> Yet, there have been no studies in humans to determine whether hyssop or any of its constituents are effective in treating HIV infection or AIDS.

### How much is usually taken?

Hyssop may be taken as a tea or tincture. The tea is prepared by infusing 2–3 teaspoons of herb in one cup (250 ml) of hot water for ten to fifteen minutes. Three cups can be drunk per day. Alternatively, 1–4 ml of tincture can be taken three times per day.<sup>8</sup> If hyssop is being used to help soothe a **sore throat** (page 129), gargle with the tea or tincture before swallowing. The essential oil should never be used at a level higher than 1–2 drops per day internally, though more can be used topically on unbroken skin. One teaspoon (5 grams) of hyssop herb steeped in 1 cup (250 ml) hot water in a closed vessel for 15–20 minutes, then given in sips from a bottle over a period of 2–3 hours, may help calm **colic** (page 121).

### Are there any side effects or interactions?

Tea and tincture of hyssop are unlikely to cause adverse effects.<sup>9</sup> Although, the volatile oil, particularly its constituent pinocamphone, has been reported to cause seizures in laboratory animals as well as in humans when taking more than 10 drops in a day or a child taking 2–3 drops over several days.<sup>10</sup> For this reason, the volatile oil should be used with extreme caution and is not recommended for those with **epilepsy** (page 183) or any other seizure disorder. The herb is not recommended during **pregnancy** (page 363).<sup>11</sup>

## IPECAC

**Botanical name:** *Cephaelis ipecacuanha*

### Parts used and where grown

Ipecac grows in the rain forests of Brazil and other parts of South and Central America. It is also cultivated to a small degree in India and Southeast Asia. Ipecac roots are used as medicine.

**Ipecac has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Poisoning
★★☆	Intestinal parasites (page 343)

### Historical or traditional use (may or may not be supported by scientific studies)

In traditional herbal medicine, ipecac appears to have been primarily used as an emetic, or an agent that induces vomiting.<sup>1</sup> The herb was reportedly first exported to Europe in 1672.<sup>2</sup> The alkaloids in the plant were identified originally in 1817.

### Active constituents

Ipecac's major constituents are the alkaloids emetine and cephaline. The roots also contain tannins and small amounts of anthraquinone glycosides.<sup>3</sup> The alkaloids have several important actions, including activation of brain centers that can induce vomiting, inhibition of the sympathetic nervous system, and inhibition of protein synthesis.<sup>4</sup>

Ipecac syrup is commonly used as a remedy for poisoning, taken following ingestion of toxic but noncaustic substances. In most people, ingestion of adequate amounts leads to vomiting within 30 minutes.<sup>5</sup>

The protein-inhibiting effects of emetine and other alkaloids of ipecac may account for the ability of the plant to inhibit growth of or kill several types of **parasites** (page 343), including ameba, pinworms, and tapeworms.<sup>6,7</sup> However, the amount of ipecac needed to produce these effects in people are high and can lead to severe side effects. Emetine or its somewhat safer form, dihydroemetine, are reserved for rare cases of people infected with amebas that are not cured by using anti-ameba drugs.<sup>8</sup> Due to the danger involved, ipecac or emetine should never be used without first consulting a physician.

### How much is usually taken?

To induce vomiting after ingesting something poisonous (after consulting with poison control centers or emergency services), adults are generally advised to take 15–30 ml of ipecac syrup followed by 3–4 glasses of water.<sup>9</sup> Children age 1–12 years should take 15 ml of ipecac syrup followed by 1–2 glasses of water. Children under age 1 year should be given 5–10 ml syrup followed by one half to 1 glass of water. The poisoned subject should be kept moving and the head kept upright after taking ipecac. It may take up to 30 minutes before vomiting occurs. A second application of 15 ml followed by more water can be used if vomiting does not occur after 30 minutes. If vomiting still does not occur after the second use, it is best to go immediately to the nearest hospital to have the ipecac pumped out of the stomach and obtain further help for the original poi-

soning. Milk or carbonated drinks should not be substituted for water after taking ipecac, as they might interfere with ipecac's absorption and efficacy. Activated charcoal will also interfere with the absorption and efficacy of ipecac. Charcoal should only be given after ipecac has caused vomiting. Ipecac should never be used to induce vomiting of caustic poisons such as gasoline, acids, or bleach. Ipecac tincture and fluid extract are much stronger than ipecac syrup. Ipecac tincture or fluid extract should never be taken in the amounts listed above for ipecac syrup.

#### **Are there any side effects or interactions?**

When used as directed for poisoning, ipecac will cause severe nausea, vomiting, and intestinal cramps. If too much ipecac is ingested, it may cause dizziness, rapid heartbeat, and palpitations. Cases have been reported of people with bulimia who abused ipecac by taking it frequently to induce vomiting and developed severe muscle damage or heart damage, and, in some cases, died.<sup>10, 11</sup> Since emetine is removed from the body slowly, the amounts can build up with repeated use and cause damage later. Ipecac should not be used during **pregnancy** (page 363) or breast-feeding.

## **IVY LEAF**

**Botanical name:** *Hedera helix*

#### **Parts used and where grown**

Ivy is an evergreen climber native to the damp woods of western, central, and southern Europe. The leaf is used medicinally.<sup>1</sup> It should be carefully distinguished from poison ivy found in the Americas.

**Ivy has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Asthma</b> (page 32) <b>Bronchitis</b> (page 80) <b>Chronic obstructive pulmonary disease</b> (page 114) (COPD)
★☆☆	<b>Cough</b> (page 139) Stretch marks (topical)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Ivy leaves were held in high regard by the ancients. They formed not only the poet's crown but also the wreath of the Greek god of wine, Dionysus. The ancient Greeks believed that binding the forehead with ivy leaves would prevent the effects of inebriation.<sup>2</sup> Greek priests presented a wreath of ivy to newlyweds, and ivy has been traditionally regarded as a symbol of fidelity. Romans regarded ivy as excellent feed for their cattle.<sup>3</sup> Traditional herbalists have used ivy for a wide number of complaints, including **bronchitis** (page 80), whooping cough, arthritis, rheumatism, and dysentery. Decoctions of the herb were applied externally against lice, scabies, and sunburn.<sup>4</sup>

#### **Active constituents**

Although ivy's composition has not been subject to detailed scientific investigations, it is known to contain 5–8% saponins.<sup>5</sup> Other constituents in the leaf include an alkaloid called emetine that is similar to one found in the herb **tylophora** (page 754). Although emetine typically induces vomiting, in ivy leaf it seems to increase the secretion of mucus in the lungs. While the emetine content is very low in ivy, this could in part explain its traditional use as an expectorant (a substance that promotes the removal of mucous from the respiratory tract).<sup>6</sup> Animal studies have shown the saponins found in ivy extract prevent the spasm of muscles in the bronchial area.<sup>7</sup>

While very few human clinical trials have been performed on ivy, a controlled trial in a group of children with bronchial **asthma** (page 32) found that 25 drops of ivy leaf extract given twice per day was effective in improving airflow into the lungs after only three days of use.<sup>8</sup> However, the incidence of **cough** (page 139) and shortness of breath symptoms did not change during the short trial period. Ivy leaf is approved by the German Commission E for use against chronic inflammatory bronchial conditions and productive coughs due to its actions as an expectorant.<sup>9</sup> One double-blind human trial found ivy leaf to be as effective as the drug ambroxol for treating the symptoms of chronic bronchitis.<sup>10</sup>

In addition to the use of ivy to treat asthma, clinical reports from Europe suggest that topical cream preparations containing ivy, **horsetail** (page 693), and lady's mantle are beneficial in reducing, although not eliminating, skin stretch marks.<sup>11</sup>

#### **How much is usually taken?**

Standardized ivy leaf extract can be taken by itself or in water at 25 drops twice per day as a supportive treat-

ment for children with **asthma** (page 32).<sup>12</sup> At least double this amount may be necessary to benefit adults with asthma. However, ivy is not intended to replace standard medical therapies and should only be used following consultation with a healthcare professional. A similar amount can be used for people with a **cough** (page 139) or **bronchitis** (page 80).

#### **Are there any side effects or interactions?**

The 0.3 gram daily tea preparation of the herb, suggested in the German Commission E monographs,<sup>13</sup> is not recommended for pediatric use because the quantities of the saponins it contains are too variable and could induce nausea and vomiting. Since ivy contains small amounts of emetine, it is not recommended during **pregnancy** (page 363), as this specific alkaloid may increase uterine contractions.<sup>14</sup> In addition, the leaf itself can be quite irritating when handled and may cause allergic skin reactions.<sup>15</sup>

## JUNIPER

**Botanical name:** *Juniperus communis*

#### **Parts used and where grown**

Juniper, an evergreen tree, grows mainly in the plains regions of Europe as well as in other parts of the world. The medicinal portions of the plant are referred to as berries, but they are actually dark blue-black scales from the cones of the tree. Unlike other pine cones, the juniper cones are fleshy and soft.

**Juniper has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Edema (water retention)</b> (page 180) <b>Indigestion</b> (page 260) <b>Urinary tract infection</b> (page 436)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Aside from being used as the flavoring agent in gin, juniper trees have contributed to the making of everything from soap to perfume.<sup>1</sup> Many conditions have

been treated in traditional herbal medicine with juniper berries, including **gout** (page 208), **warts** (page 445) and skin growths, **cancer** (page 87), **upset stomach** (page 260), and various **urinary tract** (page 436) and kidney diseases.

#### **Active constituents**

The volatile oils, particularly terpinen-4-ol, may cause an increase in urine volume.<sup>2</sup> According to some sources, juniper increases urine volume without a loss of electrolytes such as potassium.<sup>3</sup> Juniper contains bitter substances, at least partly accounting for its traditional use in digestive upset and related problems.

#### **How much is usually taken?**

The German Commission E monograph suggests  $\frac{1}{2}$ –2 teaspoons of the dried fruit daily.<sup>4</sup> To make a tea, 1 cup (250 ml) of boiling water is added to 1 teaspoon (5 grams) of juniper berries and allowed to steep for twenty minutes in a tightly covered container. Drink one cup (250 ml) each morning and night. Juniper is often combined with other diuretic and anti-microbial herbs. As a capsule or tablet, 1–2 grams can be taken three times per day, or  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–2 ml) of tincture can be taken three times daily.

#### **Are there any side effects or interactions?**

Excessive applications (greater than the amounts listed above) may cause kidney irritation. People with either acute or chronic inflammation of the kidneys or kidney failure should not use juniper. Juniper should not be taken for greater than four weeks without first consulting a healthcare professional. One report suggests that people with diabetes should use juniper cautiously as it may raise glucose levels.<sup>5</sup>

Application of the volatile oil directly to skin can cause a rash. **Pregnant** (page 363) women should avoid juniper until further information is available, as it may cause uterine contractions.

## KAVA

**Botanical name:** *Piper methysticum*

#### **Parts used and where grown**

Kava is a member of the pepper family and is native to many Pacific Ocean islands. The rhizome (underground stem) is used in modern herbal preparations.

**Warning:** Kava should be taken only with medical supervision. Kava is not for sale in certain parts of the world.

### Historical or traditional use (may or may not be supported by scientific studies)

A nonalcoholic drink made from the root of kava played an important role in social ceremonies in some Pacific islands, including welcoming visiting royalty and at meetings of village elders. Kava was valued both for its mellowing effects and to encourage socializing. It was also noted for initiating a state of contentment, a greater sense of well-being, and enhanced mental acuity, memory, and sensory perception. Kava has also been used traditionally by healers in the Pacific islands to treat **pain** (page 338).

### Active constituents

The kava-lactones, sometimes referred to as kavapyrones, are the most important active constituents in kava extracts. High-quality kava rhizome contains 5.5–8.3% kava-lactones.<sup>1</sup> Medicinal extracts used in Europe contain 30–70% kava-lactones. Kava-lactones are thought to have anti-anxiety, mild analgesic (pain-relieving), muscle-relaxing, and anticonvulsant effects.<sup>2, 3</sup> Some researchers speculate that kava may directly influence the limbic system, the ancient part of the brain associated with emotions and other brain activities.<sup>4</sup> Kava is a unique anti-anxiety alternative because it does not seem to impair reaction time or alertness when used in the amounts recommended below.<sup>5</sup>

Kava has been extensively studied as a treatment for **anxiety** (page 30).<sup>6</sup> The amount often used in clinical trials is 100 mg of an extract (standardized to 70% kava-lactones) three times per day. Double-blind trials, including one that lasted six months, have shown that kava effectively reduces symptoms of anxiety in people with mild to moderate anxiety.<sup>7, 8</sup> One trial found that kava also reduced symptoms of anxiety in menopausal women,<sup>9</sup> and in another study kava enhanced the anti-anxiety effect of hormone replacement therapy.<sup>10</sup> One trial found kava to be just as effective as benzodiazepines (a common class of drugs prescribed for anxiety) in treating mild anxiety over the course of six weeks.<sup>11</sup>

### How much is usually taken?

For treatment of mild to moderate anxiety, kava extracts supplying 120–240 mg of kava-lactones per day in two

or three divided doses are commonly recommended.<sup>12</sup> Alternatively (although it has not been researched), 1–3 ml of fresh liquid kava tincture can be taken three times per day. Kava should not be taken for more than three months without the advice of a physician, according to the German Commission E monograph.<sup>13</sup>

### Are there any side effects or interactions?

In November 2001, German authorities announced that 24 cases of liver disease (including hepatitis, liver failure, and cirrhosis) associated with the use of kava had been reported in Germany; of these, one person died and three required a liver transplant.<sup>14</sup>

Prior to this report, it had been widely believed that kava did not cause any serious side effects. The 1998 edition of the German *Commission E Monographs*, considered to be an authoritative source on herbal medicines, does not mention liver disease in its discussion of kava's side effects.<sup>15</sup> Since that time, four case reports of kava-related liver toxicity have appeared in medical journals.<sup>16, 17, 18, 19</sup> In two of these cases, severe liver failure resulted in the need for a liver transplant. Most, though not all, of the individuals who developed liver damage while taking kava were also taking at least one other medication that has been associated with liver injury.<sup>20</sup> That raises the possibility that these other drugs, rather than kava, may have been responsible for the problem in some cases. It is also conceivable that kava interacts with some of these drugs, thereby increasing their toxicity. However, some of the cases of kava-related liver disease cannot be explained by the concomitant use of other drugs.

The possibility that kava can cause liver damage is supported by a survey of an Aboriginal community in Australia. Although occasional users of kava in this community generally had normal liver function, laboratory evidence of liver injury was quite common among heavy users of the herb.<sup>21</sup> Furthermore, the risk of liver damage was directly related to the amount of kava consumed. It is not clear how relevant these findings are to other communities, since the overall health of the Aborigines who were studied was relatively poor.

It is also unclear whether kava is safe when taken in "normal" amounts. A recent survey of 400 German medical practices revealed that 78% of the kava prescriptions that were written significantly exceeded the recommended amount.<sup>22</sup> However, some of the 24 patients reported to German authorities were not exceeding the manufacturer's recommended level of intake

when they developed liver disease. In addition, in two of the four published case reports, the amount of kava used was equal to or only slightly higher than the manufacturer's recommendation.<sup>23</sup> Therefore, one cannot assume that the recommended level of intake of kava is safe for all individuals.

Health authorities worldwide are considering or implementing a ban on kava. Until additional information clarifies the extent of the risk involved, it is strongly recommended that all individuals consult their physician before taking kava. In addition, based on the available information, it seems that people with liver disease and those taking medications that have the potential to damage the liver should not take kava.

In recommended amounts, the most common side effect from kava use is mild gastrointestinal disturbances in some people. Kava may temporarily turn the skin yellow, according to some case studies.<sup>24</sup> If this occurs, people should discontinue kava use. In rare cases, an allergic skin reaction, such as a rash, may occur.<sup>25</sup> Enlargement of the pupils has also been reported after long-term use of kava.<sup>26</sup> In the amounts discussed above, kava does not appear to be addictive.

Kava is not recommended for use by **pregnant** (page 363) or breast-feeding women. It should not be taken together with other substances that also act on the central nervous system, such as alcohol, barbiturates, anti-depressants, and antipsychotic drugs. One study found that large amounts of a traditional kava preparation did worsen cognitive impairment caused by alcohol consumption.<sup>27</sup> However, at the amounts recommended above, kava does not appear to impair cognitive performance. Kava has also been reported to cause excessive sedation and grogginess when combined with benzodiazepines.<sup>28</sup> One study found it was safe to drive after taking kava at the amounts listed above.<sup>29</sup> However, the German Commission E monograph states that kava, when taken at the recommended levels, may adversely affect a person's ability to safely drive or operate heavy machinery.<sup>30</sup>

**Caution:** Aside from the reported interactions, kava inhibits a number of the cytochrome P450 enzymes that play a role in the breakdown of many medications.<sup>31</sup>

Therefore, kava has the potential to interact with a wide range of medications, even if such interactions have not yet been reported. Individuals taking any medication who wish to use kava should check with their physician or pharmacist to determine whether inhibiting cytochrome P450 could cause an adverse drug interaction.

## KUDZU

**Common name:** Ge-gen  
**Botanical name:** *Pueraria lobata*

### Parts used and where grown

Kudzu is a coarse, high-climbing, twining, trailing, perennial vine. The huge root, which can grow to the size of a human, is the source of medicinal preparations used in Traditional Chinese Medicine and modern herbal products. Kudzu grows in most shaded areas in mountains, fields, along roadsides, thickets, and thin forests throughout most of China and the southeastern United States. The root of another Asian species of kudzu, *Pueraria thomsonii*, is also used for herbal products.

**Kudzu has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Alcohol withdrawal support</b> (page 12) <b>Angina</b> (page 27)

### Historical or traditional use (may or may not be supported by scientific studies)

Kudzu root has been known for centuries in Traditional Chinese Medicine as ge-gen. The first written mention of the plant as a medicine is in the ancient herbal text of Shen Nong (circa A.D. 100). In Traditional Chinese Medicine, kudzu root is used in prescriptions for the treatment of wei, or "superficial," syndrome (a disease that manifests just under the surface—mild, but with fever), thirst, headache, and stiff neck with pain due to **high blood pressure** (page 236).<sup>1</sup> It is also recommended for **allergies** (page 14), **migraine headaches** (page 316), and **diarrhea** (page 163). The historical application for drunkenness has become a major focal point of modern research on kudzu. It is also used in modern Chinese medicine as a treatment for **angina pectoris** (page 27).

### Active constituents

Kudzu root is high in isoflavones, such as daidzein, as well as isoflavone glycosides, such as daidzin and puerarin. Depending on its growing conditions, the total isoflavone content varies from 1.77–12.0%, with puer-

arin in the highest concentration, followed by daidzin and daidzein.<sup>2</sup>

A widely publicized 1993 animal study showed that both daidzin and daidzein inhibit the desire for alcohol.<sup>3</sup> The authors concluded the root extract may in fact be useful for reducing the urge for alcohol and as treatment for **alcoholism** (page 12). However, a small controlled clinical trial with alcoholic adults taking 1.2 grams of kudzu two times per day failed to show any effect on decreasing alcohol consumption or cravings.<sup>4</sup>

#### **How much is usually taken?**

The 1985 *Chinese Pharmacopoeia* suggests 9–15 grams of kudzu root per day.<sup>5</sup> In China, standardized root extracts (10 mg tablet is equivalent to 1.5 grams of the crude root) are used to treat **angina pectoris** (page 27). Some sources recommend 30–120 mg of the extract two to three times per day.

#### **Are there any side effects or interactions?**

At the amounts recommended above, there have been no reports of kudzu toxicity in humans.

## LAVENDER

**Botanical name:** *Lavandula officinalis*

#### **Parts used and where grown**

Eastern European countries, particularly Bulgaria, as well as France, Britain, Australia, and Russia grow large quantities of lavender. The fragrant flowers of lavender are used in the preparation of herbal medicines.

**Lavender has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Pregnancy</b> (page 363) (in bath, for perineal pain after childbirth)
★☆☆	<b>Indigestion and heartburn</b> (page 260) <b>Insomnia</b> (page 270)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Traditionally, herbalists used lavender for a variety of conditions of the nervous system, including **depression**

(page 145) and fatigue.<sup>1</sup> It has also been used for headache and rheumatism. Due to its delightful odor, lavender has found wide application in perfumes and cosmetics throughout history.

#### **Active constituents**

The volatile oil (also called essential oil) of lavender contains many constituents, including perillyl alcohol and linalool. The oil is thought to be calming<sup>2</sup> and thus can be helpful in some cases of **insomnia** (page 270). One trial of elderly people with sleeping troubles found that inhaling lavender oil was as effective as some commonly prescribed sleep medications.<sup>3</sup> A large clinical trial found that lavender oil added to a bath was no more effective than a placebo for relieving perineal discomfort immediately after childbirth.<sup>4</sup> However, perineal pain was reduced three to five days afterward. Lavender is recommended by the German Commission E monograph for indigestion and nervous intestinal discomfort.<sup>5</sup>

#### **How much is usually taken?**

The German Commission E monograph suggests 1–2 teaspoons (5–10 grams) of the herb be taken as a tea.<sup>6</sup> The tea can be made by steeping 2 teaspoons (10 grams) of leaves in 1 cup (250 ml) of boiling water for fifteen minutes. Three cups (750 ml) can be consumed each day. For internal applications,  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (2–4 ml) of tincture can be taken two or three times per day. Several drops of the oil can be added to a bath or diluted in vegetable oil for topical applications. The concentrated oil is not for internal use, except under medical supervision.

#### **Are there any side effects or interactions?**

Internal use of the volatile oil can cause severe nausea. Very small amounts should be used only under the supervision of a healthcare professional. Excessive intake (several times more than listed above) may cause drowsiness.<sup>7</sup> External use in reasonable amounts is safe during **pregnancy** (page 363) and breast-feeding.

## LEMON BALM

**Common name:** Melissa

**Botanical name:** *Melissa officinalis*

#### **Parts used and where grown**

The lemon balm plant originated in southern Europe and is now found throughout the world. The lemony

smell and pretty white flowers of the plant have led to its widespread cultivation in gardens. The leaves, stems, and flowers of lemon balm are used medicinally.

**Lemon balm has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Cold sores</b> (page 119) (topical)
★★☆	<b>Alzheimer's disease</b> (page 19) <b>Colic</b> (page 121) (in combination with <b>verbena</b> [page 756], <b>licorice</b> [page 702], and <b>fennel</b> [page 676]) <b>Genital herpes</b> (page 200) (topical)
★☆☆	Grave's disease (hyperthyroidism) <b>Indigestion and heartburn</b> (page 260) <b>Infection</b> (page 265) (antiviral) <b>Insomnia</b> (page 270) Nerve pain

**Historical or traditional use (may or may not be supported by scientific studies)**

Charlemagne once ordered lemon balm planted in every monastery garden because of its beauty.<sup>1</sup> It has been used traditionally by herbalists to treat gas, sleeping difficulties, and heart problems. In addition, topical applications to the temples were sometimes used by herbalists for **insomnia** (page 270) or nerve pain.

**Active constituents**

The terpenes, part of the pleasant smelling volatile oil from lemon balm, are thought to produce this herb's relaxing and gas-relieving (carminative) effects. **Flavonoids** (page 516), phenolic acids, and other compounds appear to be responsible for lemon balm's anti-herpes and thyroid-regulating actions. Test tube studies have found that lemon balm blocks attachment of antibodies to the thyroid cells that cause Grave's disease (hyperthyroidism).<sup>2</sup> The brain's signal to the thyroid (thyroid-stimulating hormone or TSH) is also blocked from further stimulating the excessively active thyroid gland in this disease. However, clinical trials proving lemon balm's effectiveness in treating Grave's disease are lacking.

One small preliminary trial studying sleep quality compared the effect of a combination product containing an extract of lemon balm (*Melissa officinalis*) and an extract of **valerian** (page 756) root with that of the sleeping drug triazolam (Halcion). The effectiveness of the herbal combination was similar to that of Halcion,

as determined by the ability to fall asleep and the quality of sleep.<sup>3</sup> Another trial also found that the same combination of valerian and lemon balm, taken over a two-week period, is effective in improving quality of sleep.<sup>4</sup>

According to double-blind research, topical use of a concentrated lemon balm extract speeds healing time of herpes simplex virus sores (**cold sores** [page 119]) on the mouth.<sup>5,6</sup>

**How much is usually taken?**

The German Commission E monograph suggests 1.5–4.5 grams of lemon balm in a tea several times daily.<sup>7</sup> The herb can be steeped for ten to fifteen minutes in 150 ml of boiling water to make the tea. Tincture can also be used at 2–3 ml three times per day. Concentrated extracts, 160–200 mg 30 minutes to one hour before bed, are sometimes recommended for **insomnia** (page 270). Highly concentrated topical extract ointments for herpes can be applied three to four times per day to lesions.

Lemon balm is frequently combined with other medicinal plants. For example, **peppermint** (page 726) and lemon balm together are effective for calming **upset stomach** (page 260). **Valerian** (page 756) is often combined with lemon balm for insomnia. **Bugleweed** (page 647) (*Lycopus virginicus*) and lemon balm have been used together for Graves' disease.

**Are there any side effects or interactions?**

There is one published report of a severe allergic reaction (anaphylaxis) occurring in a person who took a supplement that contained willow bark.<sup>8</sup> The possibility of allergy to willow bark should be considered by anyone who is allergic to aspirin or other salicylates. As with aspirin, some people may experience stomach upset from taking willow. Although such symptoms are less likely from willow than from aspirin, people with **ulcers** (page 349) and **gastritis** (page 195) should, nevertheless, avoid this herb.<sup>9</sup> Again, as with aspirin, willow should not be used to treat fevers in children since it may cause Reye's syndrome.

## LICORICE

**Botanical names:** *Glycyrrhiza glabra*, *Glycyrrhiza uralensis*

**Parts used and where grown**

Originally from central Europe, licorice now grows all across Europe and Asia. The root is used medicinally.

**Licorice has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Infection</b> (page 265) <b>Peptic ulcer</b> (page 349) (chewable DGL)
★★☆	<b>Canker sores</b> (page 90) (DGL) <b>Colic</b> (page 121) (in combination with <b>verbena</b> [page 756], <b>fennel</b> [page 676], and <b>lemon balm</b> [page 701]) <b>Epilepsy</b> (page 183) (in combination with <b>bupleurum</b> [page 647], peony root, pinellia root, cassia bark, <b>ginger</b> [page 680] root, jujube fruit, <b>Asian ginseng</b> [page 630] root, and <b>Chinese scullcap</b> [page 658] root) <b>Gastroesophageal reflux disease</b> (page 198) (GERD) (DGL) <b>Hepatitis</b> (page 220) (intravenous glycyrrhizin) <b>HIV support</b> (page 239) <b>Infections</b> (page 265) (viral)
★☆☆	<b>Asthma</b> (page 32) <b>Chronic fatigue syndrome</b> (page 111) <b>Cold sores</b> (page 119) (topical) <b>Cough</b> (page 139) <b>Crohn's disease</b> (page 141) <b>Eczema</b> (page 177) <b>Gastritis</b> (page 195) <b>Genital herpes</b> (page 200) (topical) <b>Hay fever</b> (page 211) (Sho-seiryu-to: contains licorice, cassia bark, <b>schisandra</b> [page 744], ma huang [ephedra], <b>ginger</b> [page 680], peony root, pinellia, and asiasarum root) <b>Hepatitis</b> (page 220) (oral glycyrrhizin) <b>Indigestion and heartburn</b> (page 260) (DGL) Melasma (topical liquiritin) <b>Menopause</b> (page 311) <b>Shingles (herpes zoster)/postherpetic neuralgia</b> (page 401) (topical gel) <b>Ulcerative colitis</b> (page 433)

#### Historical or traditional use (may or may not be supported by scientific studies)

Licorice has a long and highly varied record of uses. It was and remains one of the most important herbs in Traditional Chinese Medicine. Among its most consistent and important uses are as a demulcent (soothing, coating agent) in the digestive and urinary tracts, to help with **coughs** (page 139), to soothe **sore throats** (page 129), and as a flavoring. It has also been used in Traditional Chinese Medicine to treat conditions ranging from **diabetes** (page 152) to tuberculosis.

#### Active constituents

The two major constituents of licorice are glycyrrhizin and **flavonoids** (page 516). According to test tube studies, glycyrrhizin has anti-inflammatory actions and may inhibit the breakdown of the cortisol produced by the body.<sup>1, 2</sup> Licorice may also have antiviral properties, although this has not been proven in human pharmacological studies. Licorice flavonoids, as well as the closely related chalcones, help heal digestive tract cells. They are also potent **antioxidants** (page 467) and work to protect liver cells. In test tubes, the flavonoids have been shown to kill *Helicobacter pylori*, the bacteria that causes most **ulcers** (page 349) and stomach inflammation.<sup>3</sup> However, it is unclear whether this action applies to the use of oral licorice for the treatment of ulcers in humans.

An extract of licorice, called liquiritin, has been used as a treatment for melasma, a pigmentation disorder of the skin. In a preliminary trial,<sup>4</sup> topical application of liquiritin cream twice daily for four weeks led to a 70% improvement, compared to only 20% improvement in the placebo group.

A preliminary trial found that while the acid-blocking drug cimetidine (Tagamet) led to quicker symptom relief, chewable deglycyrrhizinated licorice (DGL) tablets were just as effective at healing and maintaining the healing of stomach ulcers.<sup>5</sup> Chewable DGL may also be helpful in treating ulcers of the duodenum, the first part of the small intestine.<sup>6</sup> Capsules of DGL may not work for ulcers, however, as DGL must mix with saliva to be activated.<sup>7</sup> One preliminary human trial has found DGL used as a mouthwash was effective in quickening the healing of **canker sores** (page 90).<sup>8</sup>

#### How much is usually taken?

There are two types of licorice, "standard" licorice and "de-glycyrrhizinated" licorice (DGL). Each type is suitable for different conditions. The standard licorice containing glycyrrhizin should be used for respiratory infections, **chronic fatigue syndrome** (page 111) or herpes (topical). Licorice root in capsules, 5–6 grams per day, can be used. Concentrated extracts, 250–500 mg three times per day, are another option. Alternatively, a tea can be made by boiling  $\frac{1}{2}$  ounce (14 grams) of root in 1 pint (500 ml) of water for fifteen minutes, then drinking two to three cups (500–750 ml) per day. Long-term internal use (more than two to three weeks) of high amounts (over 10 grams per day) of glycyrrhizin-containing products should be attempted only under the supervision of a doctor. Licorice creams

or gels can be applied directly to herpes sores three to four times per day.

DGL is prepared without the glycyrrhizin in order to circumvent potential safety problems (see below), and is used for conditions of the digestive tract, such as **ulcers** (page 349). For best results, one 200–300 mg tablet is chewed three times per day before meals and before bed.<sup>9</sup> For **canker sores** (page 90), 200 mg of DGL powder can be mixed with 200 ml warm water, swished in the mouth for three minutes, and then expelled. This may be repeated three or four times per day.

#### **Are there any side effects or interactions?**

Licorice products that include glycyrrhizin may increase **blood pressure** (page 246) and cause **water retention** (page 180).<sup>10</sup> Some people are more sensitive to this effect than others. Long-term intake (more than two to three weeks) of products containing more than 1 gram of glycyrrhizin (the amount in approximately 10 grams of root) daily is the usual amount required to cause these effects. Consumption of 7 grams licorice (containing 500 mg glycyrrhizin) per day for seven days has been shown to decrease serum testosterone levels in healthy men by blocking the enzymes needed to synthesize testosterone.<sup>11</sup> However, in another study, a similar amount of licorice had only a small and statistically insignificant effect on testosterone levels.<sup>12</sup> As a result of these possible side effects, long-term intake of high levels of glycyrrhizin is discouraged and should only be undertaken if prescribed by a qualified health-care professional. Consumption of plenty of fresh fruits and vegetables to increase **potassium** (page 572) intake is recommended to help decrease the chance of side effects. According to the German Commission E monograph, licorice is inadvisable for **pregnant** (page 363) women as well as for people with liver and kidney disorders.<sup>13</sup>

De-glycyrrhizinated licorice extracts do not cause these side effects since they contain no glycyrrhizin.

## LIGUSTRUM

**Common name:** Privet

**Botanical name:** *Ligustrum lucidum*

#### **Parts used and where grown**

This shrub is native to China and eastern Asia and is now grown ornamentally in the United States. The berry of ligustrum is used medicinally.

**Ligustrum has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Immune function</b> (page 255)
	<b>Infection</b> (page 265)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Since ancient times, ligustrum berries have been employed as a “yin” tonic in Traditional Chinese Medicine.<sup>1</sup> Ligustrum was used for a wide range of conditions, including premature aging and **ringing in the ears** (page 430).<sup>2</sup>

#### **Active constituents**

The major constituent in ligustrum is ligustrin (oleanolic acid). Preliminary studies, mostly conducted in China, suggest that ligustrum stimulates the **immune system** (page 255), decreases inflammation, and protects the liver.<sup>3</sup> Ligustrum is often combined with **astragalus** (page 631) in Traditional Chinese Medicine. Although used for long-term support of the immune system in people with depressed immune function or cancer, more research is needed to demonstrate the optimal length of time to use ligustrum.

#### **How much is usually taken?**

Powdered, encapsulated berries, 1–3 teaspoons (5–15 grams) per day, are sometimes recommended.<sup>4</sup> A similar amount of berries can be made into tea by adding  $\frac{1}{2}$ –1 teaspoon (2–5 grams) of powdered or crushed berries to 1 cup (250 ml) of boiling water and steeping for ten to fifteen minutes. Alternatively,  $\frac{3}{4}$ –1 teaspoon (3–5 ml) of tincture three times per day can be taken.

#### **Are there any side effects or interactions?**

No adverse effects have been reported.

## LINDEN

**Common names:** Lime blossom, lime flower

**Botanical name:** *Tilia spp.*

#### **Parts used and where grown**

This tree grows in the northern, temperate climates of Europe, Asia, and North America. Many medicinal

species of linden exist, with *Tilia cordata* and *Tilia platyphyllos* generally being the most available and studied. Regardless of species, the flowers are used as medicine. Though sometimes called lime flower, linden is not related to the familiar green lime fruit.

**Linden has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Indigestion</b> (page 260)
★☆☆	<b>Anxiety</b> (page 30) <b>Common cold</b> (page 129) <b>Ear infection</b> (page 383)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Since time immemorial, the fragrant and tasty linden flowers have been used medicinally as a calming agent and to relieve **indigestion** (page 260), the **common cold** (page 129), and griping or colicky pain in the abdomen.<sup>1, 2</sup> Many of these uses have been confirmed or partially confirmed in modern research.

#### **Active constituents**

The major active constituents in linden are **flavonoids** (page 516), glycosides, and possibly a volatile oil. One study found that a complex mixture of compounds, primarily flavonoids, reduced anxiety in mice.<sup>3</sup> Although used as a traditional herbal remedy for **anxiety** (page 30), these results have not been confirmed in human clinical trials. Older clinical trials have shown that linden flower tea can help people with mild gallbladder problems (but not gallstones), **upset stomach** (page 260) or dyspepsia, and excessive gas that causes the stomach to push up and put pressure on the heart (also known as the gastrocardiac syndrome).<sup>4, 5</sup> Linden's reputed antispasmodic action, particularly in the intestines, has been confirmed in at least one human trial.<sup>6</sup>

Linden flowers act as a diaphoretic when consumed as a hot tea. Diaphoretics induce a mild fever, thereby possibly helping promote the immune system's ability to fight **infections** (page 265). The fever usually does not go very high because the diaphoretic also causes sweating, the body's natural way of lowering its temperature. The German Commission E has approved linden flower for the treatment of **colds** (page 129) and cold-related **coughs** (page 139).<sup>7</sup>

#### **How much is usually taken?**

A tea of linden is prepared by adding 2–3 teaspoons (5–10 grams) of dried or fresh flowers to a pint (500 ml) of just boiled water. After steeping the flowers in a covered container for ten to fifteen minutes, sip the tea while it is still hot. During an acute problem, several cups can be taken daily for up to one week.<sup>8</sup> For longer term use (three to six months), three cups (750 ml) per day can be used. A tincture or fluid extract of linden,  $\frac{1}{4}$ –1 teaspoon (3–5 ml) three times daily, may alternatively be used.

#### **Are there any side effects or interactions?**

Statements that overuse of linden can cause heart problems<sup>9</sup> lack scientific merit. Both the German Commission E monograph and the American Herbal Products Association's guide on herbal safety state that linden has no toxic effects.<sup>10, 11</sup> In fact, linden is considered safe for use in children<sup>12</sup> and there are no known reasons to avoid it during **pregnancy** (page 363) and breast-feeding.

## LOBELIA

**Common name:** Indian tobacco

**Botanical name:** *Lobelia inflata*

#### **Parts used and where grown**

*Lobelia* grows throughout North America. The leaves are primarily used in herbal medicine.

**Lobelia has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Asthma</b> (page 32) <b>Bronchitis</b> (page 80) <b>Chronic obstructive pulmonary disease</b> (page 114) (COPD) <b>Cough</b> (page 139) Smoking cessation

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Eclectic physicians, early North American doctors who used herbs as their primary medicine, considered *lobelia* to be one of the most important medicinal

plants.<sup>1</sup> It was used by Eclectics to treat **coughs** (page 139) and spasms in the lungs from varying causes, as well as spasms elsewhere in the body, including the intestines and ureters (passages from the kidney to the bladder).<sup>2</sup> Lobelia was also considered a useful pain reliever and in higher amounts was used to induce vomiting in people who had been poisoned.

### Active constituents

The alkaloid lobeline is responsible for most of lobelia's actions. Lobeline has been used as a traditional herbal approach to help people stop smoking. Results of human trials using lobeline for smoking cessation have been mixed and generally negative.<sup>3</sup> Preliminary trials suggest lobeline may improve lung function, perhaps by its abilities to reduce bronchial constriction and to thin mucus so that it can be coughed out.<sup>4</sup>

### How much is usually taken?

Eclectic physicians generally recommended using a tincture of lobelia made partially or entirely with vinegar instead of alcohol.<sup>5</sup> A vinegar extract is known as an acetate. At most, 1 ml was given three times per day. The absolute maximum amount to take should be that which causes no, or minimal, nausea. Lobelia ointment has also been used topically on the chest to relieve **asthma** (page 32) and **bronchitis** (page 80). People should apply such ointments liberally several times per day.

### Are there any side effects or interactions?

Lobelia frequently causes nausea and vomiting when the amount used is too high. Generally, more than 1 ml of tincture or acetate taken at one time will cause nausea and possibly vomiting and should be avoided.<sup>6</sup> Although lobelia has a reputation for being toxic, a thorough review of the medical literature was unable to find any well-documented case of serious problems or death due to lobelia.<sup>7</sup> This may be because a toxic amount cannot be ingested without first causing vomiting. Signs of lobelia poisoning may include weakness, heartburn, weak pulse, difficulty breathing, and collapse.<sup>8</sup> Nevertheless, lobelia should not be used for more than one month consecutively and should be avoided during **pregnancy** (page 363) and breast-feeding.<sup>9</sup> Due to its emetic (vomit-inducing) actions, lobelia should be used cautiously with children under the age of six years.

## LOMATIUM

**Botanical name:** *Lomatium dissectum*

### Parts used and where grown

Lomatium is native to western North America. Lomatium is potentially threatened in some parts of its habitat, so it should not be picked from the wild without consulting local experts familiar with the plant. The root of lomatium is used medicinally.

**Lomatium has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Infection (page 265)

### Historical or traditional use (may or may not be supported by scientific studies)

Native Americans of many tribes reportedly used lomatium root to treat a wide variety of infections, particularly those affecting the lungs.<sup>1</sup> Lomatium was used, particularly in the southwestern United States, during the **influenza** (page 269) pandemic of 1917 with reportedly good results.

### Active constituents

According to obscure sources, lomatium is reputed to have antiviral effects. One source suggests the constituents tetronic acids and a glucoside of luteolin may be potentially antiviral.<sup>2</sup> However, little is known about how these compounds act or if other ones might be as important.

### How much is usually taken?

Lomatium extracts with the resins removed (often called lomatium isolates), 1–3 ml per day, have been recommended. Lomatium tincture, 1–3 ml three times per day, can also be used, but it may cause a rash in susceptible people. The tincture should not be used unless a very small amount of it is first tested for a reaction. However, even very small amounts can cause a reaction in sensitive people.

### Are there any side effects or interactions?

Use of lomatium extracts or tinctures containing the resin (and possibly the coumarins) can, in some people,

cause a whole-body rash.<sup>3</sup> This herb may also lead to nausea in some people. The safety of lomatium during **pregnancy** (page 363) and breast-feeding is unknown and is therefore not recommended.

## MAITAKE

**Botanical name:** *Grifola frondosa*

### Parts used and where grown

Maitake is a very large mushroom, which grows deep in the mountains of northeastern Japan, as well as in North America and Europe. Famous for its taste and health benefits, maitake is also known as the “dancing mushroom.”<sup>1</sup> Legend holds that those who found the rare mushroom began dancing with joy. Others attribute its name to the way the fruit bodies of the mushroom overlap each other, giving the appearance of dancing butterflies.

Maitake is extremely sensitive to environmental changes, which have presented many challenges to those cultivating this mushroom. However, Japanese farmers have succeeded in producing high-quality organic maitake mushrooms, allowing for wider availability both in Japan and the U.S. The fruiting body and mycelium of maitake are used medicinally.

**Maitake has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>High cholesterol</b> (page 223) and <b>high triglyceride</b> (page 235) levels <b>HIV support</b> (page 239) <b>Immune function</b> (page 255) <b>Infection</b> (page 265)

### Historical or traditional use (may or may not be supported by scientific studies)

Historically, maitake has been used as a tonic and adaptogen (a substance that invigorates or strengthens the system). Along with other “medicinal” mushrooms, such as **shiitake** (page 746) and **reishi** (page 737), maitake was used as a food to help promote wellness and vitality.

### Active constituents

A common denominator among some mushrooms and some herbs is the presence of complex polysaccharides in their structure. These active constituents help support **immune system function** (page 255) and are sometimes called immunomodulators. The polysaccharides present in maitake have a unique structure and are among the most powerful studied in test tubes to date.<sup>2</sup> The primary polysaccharide, beta-D-glucan, is well absorbed when taken orally and is being studied as a potential tool for prevention and treatment of cancer and as an adjunctive treatment for **HIV infection** (page 239).<sup>3, 4</sup> Animal studies suggest maitake may lower serum cholesterol and triglycerides.<sup>5, 6</sup> However, this research is still preliminary and requires human trials for confirmation.

### How much is usually taken?

Maitake can be used as a food or tea and is also available as a capsule or tablet containing the entire fruiting body of the mushroom. For maitake, the fruit body is higher in polysaccharides than the mycelium, which is why it is recommended. Whole-mushroom maitake supplements, 3–7 grams per day, can be taken.<sup>7</sup> Liquid maitake extracts with variable concentrations of polysaccharides are available, and should be taken as directed.

### Are there any side effects or interactions?

Used as recommended above, there have been no reports of side effects with maitake.

## MALLOW

**Common names:** High mallow, common mallow

**Botanical name:** *Malva sylvestris*

Mallow

### Parts used and where grown

Mallow originates from southern Europe and Asia but has spread all over the world as a common weed. Its cousin, the dwarf mallow (*Malva neglecta*), is another Eurasian plant that has spread far and wide. Other similar plants in the same family (*Malvaceae*) are hibiscus and **marshmallow** (page 708). The dried or fresh flowers and leaves of high mallow and dwarf mallow are used as food and medicine.

**Mallow has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Cough</b> (page 139) (dry)
	<b>Dermatitis</b> (page 151) (atopic)
	<b>Sore throat</b> (page 129)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Mallow has been used as food and medicine in Europe since the time of ancient Greece and Rome. Traditional herbal medicine continues to regard the plant as a useful anti-inflammatory agent for the respiratory tract, the skin, and the gastrointestinal tract.<sup>1</sup> The esteemed German physician and herbal authority, Rudolf Weiss, MD, recommended mallow primarily for irritations of the mouth and throat, as well as for dry, irritating coughs.<sup>2</sup> He also mentions its use topically for mild cases of **eczema** (page 177).

### **Active constituents**

Like its close relative **marshmallow** (page 708) (*Althea officinalis*), mallow leaves and flowers contain high amounts of mucilage.<sup>3</sup> Mucilage, made up of complex carbohydrates, gives mallow most of its soothing activity, though flavonoids and anthocyanidins may also contribute. In herbal medicine, mallow is classified as a demulcent—a soothing agent that counters irritation and mild inflammation. Both mallow leaf and flower preparations are approved by the German Commission E for relief of **sore throats** (page 129) and dry **coughs** (page 139).<sup>4</sup> Mallow is typically used as a tea or gargle for these indications.

In test tube studies, one carbohydrate in mallow has been shown to inhibit a component of the immune system known as the complement cascade.<sup>5</sup> Excessive activation of the complement cascade has been implicated in chronic inflammation and autoimmune disorders, suggesting that further research on mallow in these areas is warranted. A polysaccharide from the seeds of a related mallow (*Malva verticillata*) stimulated white blood cells known as macrophages in a test tube study.<sup>6</sup> Crude powder of one mallow species showed anticancer effects in another test tube study.<sup>7</sup>

### **How much is usually taken?**

Mallow leaf and flower preparations are most commonly consumed as teas.<sup>8</sup> Boil 2 to 4 teaspoons of the dried leaves or flowers in 150 ml of boiling water for 10 to 15 minutes. One cup of the tea can be drunk three times per day. For topical use, a cloth can be dipped in the hot tea, allowed to cool, and then applied to inflamed skin. Alternatively, a cold infusion can be made, by soaking 6 teaspoons of the dry herb in a quart of cold water overnight, and then applied topically. According to some herbalists, the cold infusion likely extracts the plant's mucilage (a soothing, gelatinous substance) most effectively and may work best for both internal and topical use.

### **Are there any side effects or interactions?**

There are no known adverse effects from mallow when used in the amounts suggested above.

## **MARSHMALLOW**

**Botanical name:** *Althea officinalis*

### **Parts used and where grown**

The marshmallow plant thrives in wet areas and grows primarily in marshes. Originally from Europe, it now grows in the United States as well. The root and leaves are used medicinally.

**Marshmallow has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Asthma</b> (page 32)
	<b>Common cold/sore throat</b> (page 129)
	<b>Cough</b> (page 139)
	<b>Crohn's disease</b> (page 141)
	<b>Diarrhea</b> (page 163)
	<b>Gastritis</b> (page 195)
	<b>Gastroesophageal reflux disease</b> (page 198) (GERD)
	<b>Indigestion</b> (page 260)
	<b>Pap smear (abnormal)</b> (page 3)
	<b>Peptic ulcer</b> (page 349)
	<b>Ulcerative colitis</b> (page 433)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Marshmallow (not to be confused with confectionery marshmallows) has long been used by herbalists to treat **coughs** (page 139) and **sore throats** (page 129).<sup>1</sup> Due to its high mucilage content, this plant is soothing to inflamed mucous membranes. Marshmallow is also used by herbalists to soothe chapped skin, chilblains (sores caused by exposure to cold), and minor wounds.

### **Active constituents**

Mucilage, made up of large carbohydrate (sugar) molecules, is thought to be the active constituent in marshmallow. This smooth, slippery substance is believed to soothe and protect irritated mucous membranes. Marshmallow has primarily been used as a traditional herbal soothing agent for conditions of the respiratory and digestive tracts.<sup>2</sup>

### **How much is usually taken?**

The German Commission E monograph suggests 1½ teaspoon (6 grams) of the root per day.<sup>3</sup> Marshmallow can be made into a hot or cold water tea. Often 2–3 teaspoons (10–15 grams) of the root and/or leaves are used per cup (250 ml) of water. Generally, a full day's amount is steeped overnight when making a cold water tea, 6–9 teaspoons (30–45 grams) per three cups (750 ml) of water, or for fifteen to twenty minutes in hot water. Drink three to five cups (750–1250 ml) a day. Since the plant is so gooey, it does not combine well with other plants. Nevertheless, it can be found in some herbal cough syrups. Herbal extracts in capsules and tablets providing 5–6 grams of marshmallow per day can also be used, or it may be taken as a tincture—1–3 teaspoons (5–15 ml) three times daily.

### **Are there any side effects or interactions?**

Marshmallow is generally safe with only rare allergic reactions reported.

## **MEADOWSWEET**

**Botanical name:** *Filipendula ulmaria*

### **Parts used and where grown**

Meadowsweet is found in northern and southern Europe, North America, and northern Asia. The flowers

and flowering top are primarily used in herbal preparations, although there are some historical references to using the root.

### **Meadowsweet has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Common cold</b> (page 129) <b>Influenza</b> (page 139) <b>Osteoarthritis</b> (page 328) <b>Rheumatoid arthritis</b> (page 387)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Meadowsweet was used historically by herbalists for a wide variety of conditions, including treating rheumatic complaints of the joints and muscles.<sup>1</sup> Nicholas Culpeper, a 17th-century English pharmacist, mentioned its use to help break fevers and promote sweating during a **cold** (page 129) or **flu** (page 269). Traditional herbal references also indicate its use as a diuretic for people with poor urinary flow. It was also thought to have antacid properties and was used by herbalists to treat stomach complaints, including **heartburn** (page 260).

### **Active constituents**

While the flowers are high in **flavonoids** (page 516), the primary constituents in meadowsweet are the salicylates, including salicin, salicylaldehyde, and methyl salicylate.<sup>2</sup> In the digestive tract, these compounds are oxidized into salicylic acid, a substance that is closely related to aspirin (acetylsalicylic acid). While not as potent as **willow** (page 760), which has a higher salicin content, the salicylates in meadowsweet may give it a mild anti-inflammatory effect and ability to reduce fevers during a **cold** (page 129) or **flu** (page 269). However, this role is only based on historical use and knowledge of the chemistry of meadowsweet's constituents, and to date, no human trials have examined the therapeutic potential of meadowsweet.

### **How much is usually taken?**

The German Commission E monograph recommends 2.5–3.5 grams of the flower or 4–5 grams of the herb—often in a tea or infusion—per day.<sup>3</sup> Unfortunately, to

achieve an aspirin-like effect, one would realistically need to consume about 50–60 grams of meadowsweet daily. This means that **willow** (page 760) bark extracts standardized to salicin are a far more practical as a potential herbal substitute for aspirin for minor aches and **pains** (page 338) or mild fevers. Tinctures, 2–4 ml three times per day, may alternatively be used.

#### **Are there any side effects or interactions?**

People with sensitivity to aspirin should avoid the use of meadowsweet. It should not be used to lower fevers in children as it may possibly lead to Reye's syndrome.

## MILK THISTLE

**Common names:** Holy thistle, marythistle, St. Mary's thistle, Marian thistle

**Botanical names:** *Silybum marianum*, *Carduus marianus*

#### **Parts used and where grown**

Milk thistle is commonly found growing wild in a variety of settings, including roadsides. The dried fruit (also called achenes) are used to produce modern herbal extracts.

**Milk Thistle has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Alcohol-related</b> (page 12) liver disease
★★☆	<b>Hepatitis</b> (page 220) <b>Liver cirrhosis</b> (page 290)
★☆☆	<b>Gallstones</b> (page 193)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Medical use of milk thistle can be traced back more than 2,000 years. Nicholas Culpeper, the well-known 17th-century pharmacist, cited its use for opening "obstructions" of the liver and spleen and recommended it for the treatment of jaundice.

#### **Active constituents**

The dried fruit of milk thistle contain a **flavonoid** (page 516) complex known as silymarin. This constituent is responsible for the medical benefits of the plant.<sup>1</sup> Sily-

marin is made up of three parts: silibinin, silydianin, and silicristin. Silibinin is the most active and is largely responsible for the benefits attributed to silymarin.<sup>2</sup>

Milk thistle extract may protect the cells of the liver by blocking the entrance of harmful toxins and helping remove these toxins from the liver cells.<sup>3,4</sup> As with other bioflavonoids, silymarin is a powerful **antioxidant** (page 467).<sup>5</sup> Silymarin has also been shown to regenerate injured liver cells.<sup>6</sup> Recent studies have shown that silymarin has the ability to block fibrosis, a process that contributes to the eventual development of **cirrhosis** (page 290) in people with inflammatory liver conditions secondary to diseases such as **alcohol abuse** (page 12) or **hepatitis** (page 220).<sup>7</sup>

Milk thistle extract is most commonly recommended to counteract the harmful actions of alcohol on the liver. Double-blind trials indicate that it helps the liver return to a healthy state once a person stops drinking.<sup>8,9</sup> Some trials suggest it may improve quality of life and even life expectancy in people with liver cirrhosis.<sup>10,11</sup> However, another trial found no effect in cirrhosis patients.<sup>12</sup> Milk thistle alters bile makeup, thereby potentially reducing risk of **gallstones** (page 193).<sup>13</sup> However, this needs to be verified by human clinical trials. Milk thistle extract has been shown to protect the liver from the potentially damaging effect of drugs used to treat **schizophrenia** (page 393) and other forms of psychosis.<sup>14</sup> However, one trial found that it did not protect the liver from the potentially harmful effects of the drug Cognex (tacrine hydrochloride) used to treat early-stage **Alzheimer's disease** (page 19).<sup>15</sup>

#### **How much is usually taken?**

For liver disease and impaired liver function, research suggests the use of 420–600 mg of silymarin per day from an herbal extract of milk thistle standardized to 80% silymarin content.<sup>16</sup> According to research and clinical experience, improvement should be noted in about eight to twelve weeks. For people with chronic liver disease, milk thistle extract may be considered a long-term therapy.

For those who prefer, 12–15 grams of milk thistle dried fruits can be ground and eaten or made into a tea. This should not be considered therapeutic for conditions of the liver, however.

#### **Are there any side effects or interactions?**

Milk thistle extract is virtually devoid of any side effects and may be used by most people, including **pregnant** (page 363) and breast-feeding women. In fact, it

has been recommended as a treatment for itching due to poor gallbladder function during pregnancy.<sup>17</sup> Since silymarin stimulates liver and gallbladder activity, it may have a mild, transient laxative effect in some people. This will usually cease within two to three days.

There is one case report of a 57-year-old Australian woman experiencing several episodes of nausea, abdominal pain, vomiting and weakness after taking a milk thistle preparation.<sup>18</sup> This case is so atypical, however, that the Adverse Drug Reactions Advisory Committee of Australia questioned whether the product taken might not have contained other herbs or additives that could be responsible for the adverse reaction.

## MISTLETOE

**Common name:** European mistletoe

**Botanical name:** *Viscum album*

### Parts used and where grown

Mistletoe grows as a partial parasite on a variety of trees—particularly pine, apple, plum, poplar, and spruce—across northern Europe and Asia. The young leafy twigs with flowers are used. Mistletoe's white berries are potentially toxic and should be avoided. American mistletoe, various species of *Phoradendron*, are similar but have not been widely studied. They should not be substituted for European mistletoe until more information is available.

**Mistletoe has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Breast cancer (page 65)
	Diabetes (page 152)
	High blood pressure (page 246)
	HIV support (page 239)

### Historical or traditional use (may or may not be supported by scientific studies)

The ancient Druids of northern Europe and other pagan groups revered mistletoe, particularly when it

infected oak trees (a rare occurrence). Over time, this reverence of mistletoe was translated into the Christian ritual of hanging mistletoe over doorways at Christmas. The custom of kissing under the mistletoe may be a remnant of pagan orgies held before mistletoe altars.<sup>1</sup>

The name mistletoe is said to derive from the Celtic word for “all-heal.” This correlates with its historical use for everything from nervous complaints to bleeding to tumors.<sup>2</sup> It is difficult to categorize all of the uses of mistletoe, particularly when one looks at the vast number of uses for this herb in traditional Chinese and Korean medicine. In the early 20th century, Rudolf Steiner created what is known as anthroposophical medicine. This mystical system used a variety of unusual remedies, including special extracts of mistletoe for injection. Steiner helped bring mistletoe into the modern era of scientific research, particularly as a potential treatment for **cancer** (page 87).<sup>3</sup>

### Active constituents

Several constituents have been shown to contribute to the medicinal action of mistletoe. Most notable are mistletoe lectins (also called viscoxins), choline derivatives, alkaloids, polypeptides, and polysaccharides. Human pharmacological studies have found that mistletoe extract given by injection stimulates **immune system function** (page 255).<sup>4, 5, 6</sup> Some test tube and animal studies suggest that certain mistletoe constituents, including the alkaloids, can also kill cancer cells.<sup>7, 8</sup> Numerous clinical trials have found that subcutaneous injections of mistletoe extracts can help people with cancer of various organs, though some have also failed to show any benefit.<sup>9, 10</sup> There is no evidence that people with cancer would benefit from receiving mistletoe orally.

Mistletoe's other uses have been less rigorously studied. Preliminary trials carried out using oral mistletoe have found it can reduce the symptoms of **high blood pressure** (page 246), particularly headaches and dizziness.<sup>11, 12</sup> However, mistletoe has a small (if any) effect on actually lowering blood pressure.<sup>13</sup>

Test tube and animal studies suggest that mistletoe extracts can stimulate insulin secretion from pancreas cells and may improve blood sugar levels in people with **diabetes** (page 152).<sup>14, 15</sup> Given both mistletoe's tradition around the world for helping people with diabetes and these promising preclinical results, human clinical trials are needed to establish mistletoe's potential for this condition.

### **How much is usually taken?**

Traditionally a cold water extract (cold infusion) is made by soaking 2–4 teaspoons (10–20 grams) of chopped mistletoe in two cups (500 ml) of water overnight.<sup>16</sup> This is taken first thing in the morning and can be sweetened with honey. Another batch is left to steep during the day and drunk at bedtime. Alternately a hot tea can be made by infusing 1 teaspoon (5 grams) of leaves in a cup (250 ml) of just-boiled water for 5–10 minutes. Two cups (500 ml) are consumed per day.<sup>17</sup> A tincture, approximately  $\frac{1}{8}$  teaspoon ( $\frac{1}{2}$  ml) three times per day, can also be used.

At least three standardized, injectable extracts have been studied in Europe: Iscador, Helixor, and Eurixor. These products are not designed for self-treatment and are not commercially available in the United States. Iscador is the only fermented extract of the three, and each is standardized in a different way, making comparisons between the extracts difficult. In addition, there are different forms of each extract taken from mistletoe growing on different host trees. Typically, one weekly injection providing 1 mg of mistletoe lectin I per kilogram of body weight is given. People interested in subcutaneous or other injectable forms of mistletoe should consult with a physician.

### **Are there any side effects or interactions?**

In the oral amounts mentioned above, mistletoe is rarely associated with side effects.<sup>18</sup> Two reports, however, have confirmed the danger of ingesting mistletoe leaves and berries in large quantities, particularly when children accidentally eat the berries at Christmas.<sup>19, 20</sup> Many of these exposures involved American mistletoe and not European mistletoe. European mistletoe is less toxic than the American species. If six to twenty berries or four to five leaves are eaten, then activated charcoal or ipecac can be used at home to induce vomiting. Emergency room care is only indicated if more than 20 berries or five leaves are ingested or if symptoms develop at lower levels of exposure. Possible symptoms of overdose are nausea, vomiting, low blood pressure, or dizziness. Injectable forms of mistletoe may cause local redness and pain but otherwise have rarely been associated with serious side effects. There is one case report of a severe allergic reaction to an injected mistletoe preparation.<sup>21</sup> Mistletoe is not recommended for use in children, or for women during **pregnancy** (page 363) or **breastfeeding** (page 74).

## **MOTHERWORT**

**Common name:** Yi mu cao

**Botanical name:** *Leonurus cardiaca*

### **Parts used and where grown**

Motherwort came from central Eurasia originally, but has spread to all temperate areas of the world, primarily as a garden plant but also as an escaped weed. A similar plant, *Leonurus heterophyllus*, is used in China. The Chinese name for motherwort is yi mu cao, meaning “benefit mother herb.” The leaves and flowers of this mint family plant are used as medicine. In Chinese herbal medicine, the seeds are also employed.

**Motherwort has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Amenorrhea</b> (page 22) (lack of menses) <b>Anxiety</b> (page 30) <b>Menopause</b> (page 311)

### **Historical or traditional use (may or may not be supported by scientific studies)**

The use of motherwort is practically the same in European folk medicine and traditional Chinese herbal medicine. It was widely used to regulate menses and to treat associated conditions.<sup>1</sup> It was also considered a helpful diuretic and heart-strengthening herb by herbalists in both cultures, particularly to alleviate heart palpitations associated with **anxiety** (page 30) attacks.<sup>2</sup> Europeans used motherwort as a sedative as well.<sup>3</sup>

### **Active constituents**

The identities of the active constituents of motherwort are not entirely clear, though they likely include compounds in its volatile oil and the alkaloids. Little research has been done on motherwort in the West. Animal research performed in China suggests that motherwort alkaloids can calm the central nervous system and stimulate the uterus to contract.<sup>4</sup> A report suggests that preliminary human trials have found that Chinese motherwort stimulates uterine contraction after delivery and may alleviate glomerulonephritis

(kidney disease secondary to infection).<sup>5</sup> However, insufficient details were provided to assess the quality or results of these studies.

### How much is usually taken?

A tea can be prepared by steeping approximately  $\frac{1}{4}$  teaspoon (4.5 grams) of the cut herb in  $\frac{1}{2}$ – $\frac{3}{4}$  cups (150 ml) of water.<sup>6</sup> Three cups (750 ml) of the tea may be consumed daily. Alternatively, a tincture,  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (2–4 ml) three times per day, can be taken.

### Are there any side effects or interactions?

One source suggests that a single application of motherwort extract (concentration not reported) in excess of 3 grams may cause **diarrhea** (page 163), uterine bleeding, and stomach irritation.<sup>7</sup> It should be avoided in **pregnancy** (page 363) as large amounts may cause uterine contraction and potential miscarriage.<sup>8</sup>

## MULLEIN

**Botanical name:** *Verbascum thapsus*

### Parts used and where grown

Mullein is native to much of Europe and Asia and is naturalized to North America. There are over 360 species of *Verbascum* with *V. thapsus*, *V. phlomoides*, and *V. densiflorum* mentioned most often in herbal texts. The leaves and flowers are both used medicinally.

**Mullein has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Asthma</b> (page 32)
	<b>Bronchitis</b> (page 80)
	<b>Chronic obstructive pulmonary disease</b> (page 114) (COPD)
	<b>Common cold/sore throat</b> (page 129)
	<b>Cough</b> (page 139)
	<b>Ear infections</b> (page 383)

### Historical or traditional use (may or may not be supported by scientific studies)

Mullein leaves and flowers are classified in traditional herbal literature as expectorants (promotes the discharge of mucus) and demulcents (soothes irritated

mucous membranes). Historically, mullein has been used by herbalists as a remedy for the respiratory tract, particularly in cases of irritating **coughs** (page 139) with bronchial congestion.<sup>1</sup> Some herbal texts extend the therapeutic use to pneumonia and **asthma** (page 32).<sup>2</sup> Due to its mucilage content, mullein has also been used topically by herbalists as a soothing emollient for inflammatory skin conditions and burns.

### Active constituents

Mullein contains approximately 3% mucilage and small amounts of saponins and tannins.<sup>3</sup> The mucilaginous constituents are thought to be responsible for the soothing actions on mucous membranes. The saponins may be responsible for the expectorant actions of mullein.<sup>4</sup> Human clinical trials are lacking to confirm the use of mullien for any condition, however.

### How much is usually taken?

A tea of mullein is made by pouring 1 cup (250 ml) of boiling water over 1–2 teaspoons (5–10 grams) of dried leaves or flowers and steeping for ten to fifteen minutes. The tea can be drunk three to four times per day. For the tincture,  $\frac{1}{4}$ – $\frac{3}{4}$  teaspoon (1–4 ml) is taken three to four times per day. As a dried product,  $\frac{1}{4}$ – $\frac{3}{4}$  teaspoon (3–4 grams) is used three times per day.<sup>5</sup> Mullein is sometimes combined with other demulcent or expectorant herbs when used to treat **coughs** (page 139) and bronchial irritation. For **ear infections** (page 383), some doctors apply an oil extract directly in the ear. If the eardrum has ruptured, nothing should be put directly in the ear. Therefore, a qualified healthcare professional should always do an ear examination before mullein oil is placed in the ear.

### Are there any side effects or interactions?

Mullein is generally safe except for rare reports of skin irritation. There are no known reasons to avoid its use during **pregnancy** (page 363) or breast-feeding.

## MYRRH

**Botanical name:** *Commiphora molmol*

### Parts used and where grown

Myrrh grows as a shrub in desert regions, particularly in northeastern Africa and the Middle East. The resin obtained from the stems is used in medicinal preparations.

**Myrrh has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Gingivitis</b> (page 203) (periodontal disease) (as mouthwash, in combination with <b>sage</b> [page 740], <b>peppermint</b> [page 726] oil, menthol, <b>chamomile</b> [page 656] tincture, expressed juice from <b>echinacea</b> [page 669], clove oil, and <b>caraway</b> [page 651] oil) <b>Parasites</b> (page 343) (schistosomiasis)
★★☆	<b>Canker sores</b> (page 90) <b>Cold sores</b> (page 119) <b>Common cold/sore throat</b> (page 129) <b>Halitosis</b> (page 209) (rinse) <b>Infection</b> (page 265) <b>Pap smear (abnormal)</b> (page 3) <b>Ulcerative colitis</b> (page 433)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

In ancient times, the red-brown resin of myrrh was used to preserve mummies. It was also used as a remedy for numerous infections, including leprosy and syphilis. Myrrh was also recommended by herbalists for relief from **bad breath** (page 209) and for dental conditions.<sup>1</sup> In Traditional Chinese Medicine, it has been used to treat bleeding disorders and **wounds** (page 319).

#### **Active constituents**

The three main constituents of myrrh are the resin, the gum, and the volatile oil. All are thought to be important in myrrh's activity as an herbal medicine. The resin has reportedly been shown to kill various microbes and to stimulate macrophages (a type of white blood cell) in test tube studies.<sup>2</sup> Myrrh also has astringent properties and has a soothing effect on inflamed tissues in the mouth and throat. Studies continue on the potential anticancer and pain-relieving actions of myrrh resin.<sup>3, 4</sup> Human clinical trials are lacking to confirm most uses of myrrh.

In a preliminary trial, patients with schistosomiasis (a parasitic infection) were treated with a combination of resin and volatile oil of myrrh, in the amount of 10 mg per 2.2 pounds of body weight per day for three days. The cure rate was 91.7% and, of those who did not respond, 76.5% were cured by a second six-day course of treatment, increasing the overall cure rate to 98.1%.<sup>5</sup>

#### **How much is usually taken?**

The German Commission E monograph recommends that persons either dab the undiluted tincture in the mouth or gargle with 5–10 drops of tincture in a glass of water three times daily.<sup>6</sup> In addition, tincture of myrrh, 1–2 ml three times per day, can be taken. The tincture can also be applied topically for **canker sores** (page 90). Due to the gummy nature of the product, a tea cannot be made from myrrh. Capsules, containing up to 1 gram of resin taken three times per day, can be used as well.

#### **Are there any side effects or interactions?**

No adverse effects from myrrh usage have been reported.

## NETTLE

**Botanical name:** *Urtica dioica*

#### **Parts used and where grown**

Nettle is a leafy plant that is found in most temperate regions of the world. The Latin root of *Urtica* is *uro*, meaning "I burn," indicative of the small stings caused by the little hairs on the leaves of this plant that burn when contact is made with the skin. The root and leaves of nettle are used in herbal medicine.

#### **Nettle has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Benign prostatic hyperplasia</b> (page 58) (root extract) <b>Osteoarthritis</b> (page 328)
★★☆	<b>Hay fever</b> (page 211) <b>Pregnancy and postpartum support</b> (page 363) <b>Rheumatoid arthritis</b> (page 387) <b>Urinary tract infection</b> (page 436)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Nettle has a long history of use. The tough fibers from the stem have been used to make cloth and cooked nettle leaves were eaten as vegetables. From ancient Greece to the present, nettle has been documented for its tradi-

tional use in treating **coughs** (page 139), tuberculosis, and arthritis and in stimulating hair growth.

### Active constituents

There has been a great deal of controversy regarding the identity of nettle's active constituents. Currently, it is thought that polysaccharides (complex sugars) and lectins are probably the active constituents. Test tube studies suggest the leaf has anti-inflammatory actions. This is thought to be caused by nettle preventing the body from making inflammatory chemicals known as prostaglandins.<sup>1</sup> Nettle's root affects hormones and proteins that carry sex hormones (such as testosterone or estrogen) in the human body. This may explain why it helps **benign prostatic hyperplasia** (page 58) (BPH).<sup>2</sup> Although less frequently used alone like **saw palmetto** (page 743) or **pygeum** (page 734), some limited clinical trials suggest benefit of nettle root extract for men with milder forms of BPH.<sup>3</sup>

A preliminary trial reported that capsules made from freeze-dried leaves reduced sneezing and itching in people with **hay fever** (page 211).<sup>4</sup> Further studies are needed to confirm this finding, however.

The historical practice of intentionally applying nettle topically with the intent of causing stings to relieve arthritis has been assessed by a questionnaire in modern times.<sup>5</sup> The results found intentional nettle stings safe, except for a sometimes painful, sometimes numb rash that lasts 6–24 hours. Additional trials are required to determine if this practice is therapeutically effective.

### How much is usually taken?

During the **allergy** (page 14) season, two to three 300 mg nettle leaf capsules or tablets or 2–4 ml tincture can be taken three times per day. For **BPH** (page 58), 120 mg of a concentrated root extract in capsules can be taken two times per day.<sup>6</sup> Many products for BPH will combine nettle root with **saw palmetto** (page 743) or **pygeum** (page 734) extracts. Intentional stinging with nettles should only be undertaken after consultation with a physician knowledgeable in botanical medicine.

### Are there any side effects or interactions?

Nettle may cause mild gastrointestinal upset in some people. Although allergic reactions to nettle are rare, when contact is made with the skin, fresh nettle can cause a rash secondary to the noted stings.<sup>7</sup> Nettle leaf is considered safe for use in **pregnancy** (page 363) and breast-feeding.

## NONI

**Common name:** Indian mulberry

**Botanical name:** *Morinda citrifolia*

### Parts used and where grown

Native to Polynesia, the noni plant (also known as Indian mulberry) is a small tree that usually grows to a height of ten feet. The fruit, which starts out green and turns yellow, is used medicinally.

**Noni has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Immune enhancement (page 255)

### Historical or traditional use (may or may not be supported by scientific studies)

Traditional Polynesian healers have used the fruit of the noni plant for just about everything—from a tonic drink to mending broken bones—but it is said that because of its strong, unpleasant odor and bitter taste, a person won't take it until they are too sick and desperate. The bark yields a red dye while the root yields a yellow one. Both colors were used in the ceremonial outfits of Hawaiian chiefs. In the early 1990s, noni juice became heavily marketed in the United States primarily through network marketing companies. However, despite tremendous claims and testimonials, there is little scientific documentation on noni.

### Active constituents

The major constituents in noni appear to be polysaccharides and a compound known as damnacanthal.<sup>1, 2, 3</sup> The developer of a commercial noni product claims the alkaloid xeronine is an important constituent, but there has been no confirmation by independent researchers. Animal and test tubes studies show noni to have **immune-enhancing** (page 255) activity, and an earlier animal study seemed to indicate the fruit exerts a mild sedative effect.<sup>4, 5, 6</sup> Specifically, the polysaccharide component has been shown to increase the release of immune-enhancing compounds that activate white blood cells. Also, damnacanthal is thought to be responsible for producing sedative effects in animal studies.

### How much is usually taken?

The usual recommendation is 4 ounces (120 ml) of noni juice 30 minutes before breakfast (effectiveness is thought to be best on an empty stomach). Commercial products are now available that have either eliminated the odor, altered the taste, or made it available as an extract in tablets or capsules to increase palatability. For liquid concentrates the typical recommendation is 2 tablespoons (30 ml) per day. For powdered extracts the typical recommendation is 500 to 1,000 mg daily.

### Are there any side effects or interactions?

There have been no commonly reported side effects following the ingestion of noni. Since the use of noni during **pregnancy** (page 363) and breast-feeding has not been adequately studied, it is recommended that it not be used during these times.

## OAK

**Botanical name:** *Quercus* spp.

### Parts used and where grown

Oak trees grow throughout North America. Some species of oak grow around the world, including in China and the Middle East. The bark of the oak tree is used medicinally.

**Oak has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Canker sores (page 90)
	Crohn's disease (page 141)
	Diarrhea (page 163)
	Eczema (page 177)
	Menorrhagia (page 314)

### Historical or traditional use (may or may not be supported by scientific studies)

Oak bark was used traditionally by herbalists to treat **hemorrhoids** (page 219), **varicose veins** (page 440), **diarrhea** (page 163), and **cancer** (page 87). Tannic acid derived from oak trees has a long history of application in tanning hides and making ink.<sup>1</sup>

### Active constituents

Tannins are the primary constituents of oak bark.<sup>2</sup> These tannins are potent astringents, akin to those found in **witch hazel** (page 760) (*Hamamelis virginiana*). Tannins bind liquids, absorb toxins, and soothe inflamed tissues. The oak tannin, known as ellagitannin, inhibits intestinal secretion,<sup>3</sup> which helps resolve **diarrhea** (page 163). The nonirritating, astringent nature of oak has led to its recommendation for treating mild, acute diarrhea in children (along with plenty of electrolyte-containing fluids) in Europe.<sup>4</sup> Astringents such as oak may also help relieve the pain of **sore throats** (page 129) and **canker sores** (page 90).

### How much is usually taken?

The German Commission E monograph suggests  $\frac{1}{2}$  teaspoon (3 grams) of the bark per day.<sup>5</sup> For **eczema** (page 177), oak is applied topically by first boiling 1–2 tablespoons (15–30 grams) of the bark for fifteen minutes in 2 cups (500 ml) of water. After cooling, a cloth is dipped into the liquid and applied directly to the rash several times per day. The liquid prepared this way in the morning can be used throughout the day. Unused portions should then be discarded. Up to 5 cups (1250 ml) of this same solution can be taken each day in cases of **diarrhea** (page 163). Alternatively, a tincture of oak, approximately  $\frac{1}{2}$  teaspoon (2–3 ml) three times daily, can be used.

### Are there any side effects or interactions?

Except for the occasional upset stomach or **constipation** (page 137) reported after drinking the tea, oak bark is rarely associated with side effects. There are no known reasons to avoid oak during **pregnancy** (page 363) or breast-feeding, though oak can cause constipation. It is safe for use in children and infants. The German Commission E monograph warns against people with open sores, **wounds** (page 319), high fever, or **infection** (page 265) bathing in water with oak bark.<sup>6</sup>

## OATS

**Common name:** Wild oats

**Botanical name:** *Avena sativa*

### Parts used and where grown

The common oat used in herbal supplements and foods is derived from cultivated sources. For some herbal supplements, the green or rapidly dried aerial parts of the

plant are harvested just before reaching full flower. Many herbal texts refer to using the fruits (seeds) or green tops. Although some herb texts discuss oat straw, there is little medicinal action in this part of the plant.

**Oats have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>High triglycerides</b> (page 235)
★☆☆	<b>Anxiety</b> (page 30) <b>Eczema</b> (page 177) Nicotine withdrawal

**Historical or traditional use (may or may not be supported by scientific studies)**

In folk medicine, oats are used by herbalists to treat nervous exhaustion, **insomnia** (page 270), and “weakness of the nerves.” A tea made from oats was thought by herbalists to be useful in rheumatic conditions and to treat **water retention** (page 180). A tincture of the green tops of oats was also used to help with withdrawal from tobacco addiction.<sup>1</sup> Oats were often used in baths to treat insomnia and **anxiety** (page 30) as well as a variety of skin conditions, including **burns** (page 85) and **eczema** (page 177).

**Active constituents**

The fruits (seeds) contain alkaloids, such as gramine and avenine, and saponins, such as avenacosides A and B.<sup>2</sup> The seeds are also rich in **iron** (page 540), **manganese** (page 553), and **zinc** (page 614). The straw is high in silica. Oat alkaloids are believed to account for the relaxing action of oats, but it should be noted this continues to be debated in Europe. The German Commission E does not approve this herb as a sedative.<sup>3</sup> However, an alcohol-based tincture of the fresh plant has reportedly shown some promise in countering nicotine withdrawal and helping with smoking cessation.<sup>4</sup>

**How much is usually taken?**

A tea can be made from a heaping tablespoonful (approximately 15 grams) of oats brewed with 1 cup (250 ml) of boiling water. After cooling and straining, the tea can be taken several times a day and shortly before going to bed.<sup>5</sup> As a tincture, oats are often taken at  $\frac{1}{2}$ –1 teaspoon (3–5 ml) three times per day. Capsules or tablets, 1–4 grams per day, can be taken. A soothing

bath to ease irritated skin can be made by running the bath water through a sock containing several tablespoons of oats, then bathing in the water for several minutes.

**Are there any side effects or interactions?**

Oats are not associated with any adverse effects.

## OLIVE LEAF

**Botanical name:** *Olea europaea*

**Parts used and where grown**

Olive is a small evergreen tree native to Mediterranean regions. The characteristic green to blue-black fruit of this tree yields a useful, edible oil. Both the oil and the dried green-grayish colored leaves are used medicinally.<sup>1,2</sup>

**Olive leaf has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Diabetes</b> (page 152) <b>High blood pressure</b> (page 246) <b>Infection</b> (page 265)

**Historical or traditional use (may or may not be supported by scientific studies)**

The olive tree has been held in high esteem throughout history. Moses reportedly decreed that men who cultivated the leaf be exempt from serving in the army. The oil is symbolic of purity and goodness, while the olive branch represents peace and prosperity. Winners in the Greek Olympic games were crowned with a wreath of olive leaves.<sup>3</sup> Historically, medicinal use of olive leaf has been for treatment of fevers and for the topical treatment of **wounds** (page 319) or **infection** (page 265). As a poultice, it was also used by herbalists to treat skin rashes and boils.<sup>4</sup>

**Active constituents**

Olive leaf has a wide number of constituents, including oleuropein and several types of **flavonoids** (page 516) (e.g., rutin, apigenin, luteolin).<sup>5</sup> While olive leaf is tra-

ditionally associated with a wide number of medicinal claims, few of these have been verified by experimental study. In an animal study oleuropein (when given by injection or in intravenous form) was found to decrease blood pressure (e.g., systolic and diastolic) and dilate the coronary arteries surrounding the heart.<sup>6</sup> This ability to lower blood pressure may justify the traditional use of olive leaf in the treatment of mild to moderate **hypertension** (page 246).<sup>7</sup> However, human studies are needed to clearly establish olive leaf as a potential treatment for high blood pressure.

In addition, a test tube study has revealed that oleuropein inhibits the oxidation of LDL ("bad") cholesterol. LDL oxidation is one part in a series of damaging events that, if left unchecked, can lead to the development of atherosclerosis.<sup>8</sup> This action may provide one clue as to why those consuming a Mediterranean-based diet may lower their risk of developing **atherosclerosis** (page 38).

Oleuropein from olives may also have antibacterial properties. When unheated olives are brined to preserve them, oleuropein is converted into another chemical called elenolic acid. Elenolic acid has shown antibacterial actions against several species of *Lactobacilli* and *Staphylococcus aureus* and *Bacillus subtilis* in a test tube study.<sup>9</sup> Whether or not the oleuropein in the leaf undergoes such a transformation is open to question at this point, raising some question as to its antibacterial effects and potential use for this purpose in humans.

Olive leaf extracts have been employed experimentally to lower elevated blood-sugar levels in animals with diabetes.<sup>10</sup> These results have not been reproduced in human clinical trials and as such, no clear conclusions can be made from this animal study in the treatment of **diabetes** (page 152).

#### How much is usually taken?

The effective amount of olive leaf for human use is not established. To make a tea, steep 1 teaspoon (5 grams) of dried leaves in 1 cup (250 ml) of hot water for 10–15 minutes.<sup>11</sup> Dried leaf extracts containing 6–15% oleuropein are available commercially, but no standard amount has been established.

#### Are there any side effects or interactions?

The safety of olive leaf has not been established in **pregnancy** (page 363). Olive leaf can be irritating to the stomach lining and should be taken with meals.<sup>12</sup>

## ONION

**Botanical name:** *Allium cepa*

#### Parts used and where grown

Like its close cousins **garlic** (page 679), chives, scallions, and leeks, onion is a member of the lily family (Liliaceae). It is native to Eurasia but now grows all over the world, due mostly to people bringing it with them as a staple food wherever they migrated. The French explorer Pere Marquette was saved from starvation in 1624 by eating wild onions near the present site of Chicago—the name of the city is derived from a Native American word for the odor of onions.<sup>1</sup> The bulb of the plant is used medicinally.

**Onion has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Atherosclerosis</b> (page 38) <b>Cancer prevention</b> (page 87) <b>Diabetes</b> (page 152) Hyperlipidemia
★☆☆	<b>Asthma</b> (page 32) <b>Cough</b> (page 139) <b>Eczema</b> (page 177) <b>Hypertension</b> (page 246) <b>Infection</b> (page 265)

#### Historical or traditional use (may or may not be supported by scientific studies)

Onion has been used as food for many centuries.<sup>2</sup> Onion was also a popular folk remedy, being applied to tumors, made into a syrup for relieving **coughs** (page 139), or prepared in a tincture (using gin) to relieve "dropsy" (heart failure-related edema).<sup>3</sup> It was considered a weaker version of **garlic** (page 679) by many herbal practitioners. Like garlic, onion has a longstanding but unsubstantiated reputation as an aphrodisiac.<sup>4</sup>

#### Active constituents

Two sets of compounds make up the majority of onion's known active constituents—sulfur compounds, such as allyl propyl disulphide (APDS), and **flavonoids** (page 516), such as **quercetin** (page 580). Each of these groups of compounds has multiple medicinal actions.

The sulfur compounds form a strongly scented oil,

particularly the compound known as thiopropanal-s-oxide or lacrimatory factor. It is responsible for the tearing many people suffer while cutting onions.<sup>5</sup> Onion and onion oil constituents have been repeatedly shown to kill various microbes in the test tube.<sup>6,7</sup> Studies have not been conducted in humans to determine whether onion is a useful antimicrobial agent.

APDS has been shown to block the breakdown of insulin by the liver and possibly to stimulate insulin production by the pancreas, thus increasing the amount of insulin and reducing sugar levels in the blood.<sup>8</sup> Several uncontrolled human studies<sup>9,10</sup> and at least one double-blind clinical trial<sup>11</sup> have shown that large amounts of onion can lower blood sugar levels in people with **diabetes** (page 152). Onion does not reduce blood sugar levels in healthy nondiabetic people.<sup>12</sup>

Sulfur compounds in onion oil have also been shown to be anti-inflammatory, both by inhibiting formation of thromboxanes and by inhibiting the action of platelet-activating factor (PAF).<sup>13,14</sup> Not all studies have confirmed that these actions occur in humans.<sup>15</sup> The anti-inflammatory effect is strong enough that subcutaneous onion injections and topical onion applications inhibit skin reactions to intensely inflammatory compounds in people with or without **eczema** (page 177), according to the results of one double-blind study.<sup>16</sup> Human studies have not been performed to determine whether onion would be useful in people with **asthma** (page 32) or **cough** (page 139), though the anti-inflammatory action cited above suggests it might be. These actions, coupled with an ability to reduce the stickiness of platelets<sup>17</sup> and, overall, to decrease the thickness of the blood,<sup>18</sup> have led to interest in onion as a way to prevent or possibly reduce **atherosclerosis** (page 38).

Human studies have proven mixed as to whether onion is helpful for people with atherosclerosis.<sup>19</sup> Intake of quercetin in the diet, primarily from onion, tea, and apples, has been linked to a decreased risk of having a heart attack.<sup>20</sup> High intake of quercetin and other flavonoids from onion and other foods has been shown to decrease risk of atherosclerosis in an epidemiologic study in the United States, although the result was not considered statistically significant.<sup>21</sup> One open clinical trial showed that a crude onion extract could lower blood pressure in some people with **hypertension** (page 246).<sup>22</sup> On the whole, it is unclear whether or not onion supplements, as opposed to onions eaten as food, have a beneficial effect on heart disease.

In a preliminary study of healthy male volunteers, administration of 50 grams of raw or boiled onion pre-

vented the rise in serum cholesterol induced by consumption of a high-fat meal.<sup>23</sup>

The evidence on **cancer prevention** (page 87) with onion suggests a benefit for some but not necessarily for all types of cancer. Onion consumption at a level of at least half an onion a day was associated with a 50% decline in stomach cancer risk in one study.<sup>24</sup> Higher onion intake was also correlated with lower risk of breast cancer in a French epidemiological study.<sup>25</sup> No protective effect against colorectal cancer was seen from higher onion intake.<sup>26</sup>

### How much is usually taken?

Most human studies that have shown an effect from onions used at least 25 grams per day and often two to four times that amount.<sup>27,28</sup> Though some studies have found cooked onions acceptable, several studies suggest that onion constituents are degraded by cooking and that fresh or raw onions are probably most active.<sup>29,30,31,32</sup> If a tincture, syrup, or oil extract is used, 1 tablespoon three times per day may be necessary for several months before effects are noted.<sup>33</sup>

### Are there any side effects or interactions?

Most people can eat onion in food without any difficulties. Higher intakes of onion may worsen existing **heartburn** (page 260), though it does not seem to cause heartburn in people who do not already have it.<sup>34</sup> There are also isolated reports of **allergy** (page 14) to onion, including among people with **asthma** (page 32),<sup>35</sup> manifesting as skin rash and red, itchy eyes.

Onion is safe for use in children and, in small amounts in food, during pregnancy (though some pregnant women may have heartburn that onions could exacerbate) and nursing. It is unknown whether larger amounts of onion are safe during pregnancy and nursing. One study did find that baby rats nursing from mothers that were fed onion developed a taste for onion and suffered no ill effects.<sup>36</sup>

## OREGANO/WILD MARJORAM

**Botanical name:** *Origanum vulgare*

### Parts used and where grown

Oregano is an aromatic perennial herb that can grow to about two feet in height. It is native to the Mediter-

ranean region but is cultivated worldwide. In addition to European oregano, there are several types of related species, including Greek/Turkish oregano (*Origanum onites*) and Mexican oregano (*Lippia graveolens*, *Lippa palmeri*). These should not be considered substitutes for true oregano, though they may have similar properties. The leaves as well as the volatile oil of these various species are used medicinally, but must be carefully distinguished as they are quite different.<sup>1</sup>

**Oregano has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Athlete's foot</b> (page 42) (oil topically) <b>Chronic candidiasis</b> (page 109) (oil internally) <b>Indigestion</b> (page 260) (leaf tea) <b>Infection</b> (page 265) (oil internally) Ringworm (tinea) (oil internally) <b>Yeast infection</b> (page 454)

**Historical or traditional use (may or may not be supported by scientific studies)**

The name *Origanum* is the contraction of two Greek words, *oros* meaning mountain and *ganos* meaning joy. Together the words suggest the beauty that oregano lends to the fields and hilltops on which it grows.<sup>2</sup> Oregano was used extensively by the Greeks for conditions ranging from convulsions to heart failure. Nineteenth-century American Eclectic physicians (doctors who recommended herbal medicines) employed oregano as both a general tonic and to promote menstruation.<sup>3</sup>

**Active constituents**

This dried herb contains several constituents, including volatile oil (up to 3%), such as carvacrol, thymol, and borneol, plus **flavonoids** (page 516), rosmarinic acid, triterpenoids (e.g., ursolic and oleanolic acid), sterols, and **vitamin A** (page 595) and **vitamin C** (page 604).<sup>4</sup> The thymol and carvacrol contents in oregano are responsible for its antimicrobial and antifungal effects.<sup>5</sup> A test tube study demonstrated that oil of oregano, and carvacrol in particular, inhibited the growth of *Candida albicans* far more effectively than a commonly employed antifungal agent called calcium magnesium caprylate.<sup>6</sup> Clinical studies are still needed to confirm these actions in humans.

In addition to its anti-fungal action, and according to the results of another test tube study from Australia,

oregano oil has a strong anti-microbial action against a wide number of bacteria, including *Escherichia coli*, *Klebsiella pneumoniae*, *Salmonella enterica*, and *Staphylococcus aureus*.<sup>7</sup> Other test tube studies have shown that oregano from the Mexican (*Lippia*) species was more effective than the prescription medication tinidazol in inhibiting the parasite giardia (*Giardia duodenalis*).<sup>8</sup> In another test tube study, volatile oils of oregano, **thyme** (page 52), **cinnamon** (page 659), and cumin were individually able to stop the growth of another food-borne pathogen called *Aspergillus parasiticus*. Higher concentrations of these volatile oils were also able to stop the production of aflatoxin, a potent poison from the food mold *Aspergillus*.<sup>9</sup> Together these facts suggest the volatile oils in oregano used during food processing have an important role in preventing the spoilage of food and in reducing the risk of ingesting harmful bacteria, fungi, and **parasites** (page 343). Again, these actions have not yet been confirmed by human clinical trials.

The German Commission E does not approve oregano for any medical indication.<sup>10</sup>

**How much is usually taken?**

Dried or fresh leaf of oregano can be made into a tea by steeping 1 to 2 teaspoons (5 to 10 grams) in hot water for ten minutes. This tea can be consumed three times a day.<sup>11</sup> The oil (50% or greater dilution) may be applied topically twice a day to areas affected by athlete's foot or other fungal infections. The affected area should be covered by the oil with each application. The safety of the internal use of the oil has not been well studied and should be used with caution or after consulting with a healthcare professional.

**Are there any side effects or interactions?**

Oregano leaf is very safe. The German Commission E and American Herbal Products Association both state there are no known risks with oregano leaf;<sup>12</sup> neither of these references mentions oregano oil.

Due to the lack of human research and the highly concentrated nature of oregano volatile oil, there is potential for harm from its use; therefore, until its internal use in humans has been proven safe, it should taken with caution if not recommended by a healthcare professional.<sup>13</sup> Volatile oils are generally considered contraindicated in **pregnancy** (page 363) as they likely reach the baby and may cause harm.<sup>14</sup> Topically, the volatile oil of oregano may be moderately irritating to skin and can be a potent mucous membrane ir-

ritant. It should not be applied topically to mucous membranes in greater than a 1% concentration.<sup>15</sup> Children less than two years of age and people with damaged or very sensitive skin should not use the oil topically.<sup>16</sup>

## OREGON GRAPE

**Botanical name:** *Berberis aquifolium*

### Parts used and where grown

Oregon grape is an evergreen shrub which grows throughout the American northwest. It is somewhat misnamed, as the fruit are not actually grapes. It is, however, grown in Oregon (it is the official state flower). Oregon grape is a close relative of **barberry** (page 632) (*Berberis vulgaris*), and shares many common uses and constituents. The root is used medicinally.

**Oregon grape has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Chronic candidiasis</b> (page 109) <b>Conjunctivitis/blepharitis</b> (page 136) <b>Diarrhea</b> (page 163) <b>Infection</b> (page 265) <b>Parasites</b> (page 343) <b>Poor digestion</b> (page 260) <b>Psoriasis</b> (page 379) <b>Urinary tract infections</b> (page 436)

### Historical or traditional use (may or may not be supported by scientific studies)

Before European colonists arrived, the indigenous peoples of North America treated all manner of complaints with Oregon grape.<sup>1</sup> The berries were used for poor appetite. A tea made from the root was used to treat jaundice, arthritis, **diarrhea** (page 163), fever, and many other health problems.

### Active constituents

Alkaloids, including berberine, berbamine, canadine, and hydrastine, may account for the activity of Oregon grape. Isolated berberine has been shown to effectively

treat **diarrhea** (page 163) in patients infected with *E. coli*.<sup>2</sup> One of the ways berberine may ease diarrhea is by slowing the transit time in the intestine.<sup>3</sup> Berberine inhibits the ability of bacteria to attach to human cells, which helps prevent **infections** (page 265), particularly in the throat, intestines, and **urinary tract** (page 436).<sup>4</sup> These actions, coupled with berberine's ability to enhance **immune cell function** (page 255),<sup>5</sup> make Oregon grape possibly useful for mild infections although clinical trials are lacking on the whole root.

In one clinical trial, an ointment of Oregon grape was found to be mildly effective for reducing skin irritation, inflammation and itching in people with mild to moderate **psoriasis** (page 379).<sup>6</sup> Whole Oregon grape extracts were shown in one pharmacological study to reduce inflammation (often associated with psoriasis) and stimulate the white blood cells known as macrophages.<sup>7</sup> In this study, isolated alkaloids from Oregon grape did not have these actions. This suggests that something besides alkaloids are important to the properties of Oregon grape responsible for reducing inflammation.

The bitter-tasting compounds as well as the alkaloids in Oregon grape root are thought to stimulate **digestive function** (page 260).

### How much is usually taken?

A tea can be prepared by boiling 1–3 teaspoons (5–15 grams) of chopped roots in 2 cups (500 ml) of water for fifteen minutes. After straining and cooling, 3 cups (750 ml) can be taken per day. Tincture,  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (3 ml) three times per day, can be used. Since berberine is not well absorbed, Oregon grape root might not provide adequate amounts of this compound to treat significant systemic **infections** (page 265). A physician should be consulted in the case of infection before attempting to use Oregon grape. An ointment made with 10% Oregon grape extract applied three or more times daily may be useful for **psoriasis** (page 379).

### Are there any side effects or interactions?

Oregon grape is thought to be safe in the amounts indicated above. Long-term (more than two to three weeks) internal use is not recommended. Berberine alone has been reported to interfere with normal bilirubin metabolism in infants, raising a concern that it might worsen jaundice.<sup>8</sup> For this reason, berberine-containing plants should be used with caution during **pregnancy** (page 363) and breast-feeding.

## PASSION FLOWER

**Botanical name:** *Passiflora incarnata*

### Parts used and where grown

Passion flower is a climbing vine renowned for its beautiful white flowers with purple, blue, or pink calyx crown blooms. The plant is native to North, Central, and South America. While primarily tropical, some of its 400 species can grow in colder climates. The mystery of such a beautiful blossom emerging from an unassuming bud has been compared to the Passion of Christ. This inspired the plant's name, which dates back to the 17th century. The leaves, stems, and flowers are used for medicinal purposes.

**Passion flower has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Anxiety</b> (page 30)
★★★	<b>Insomnia</b> (page 270) <b>Pain</b> (page 338)

### Historical or traditional use (may or may not be supported by scientific studies)

The historical use of passion flower is not dissimilar to its current use as a mild sedative. Medicinal use of the herb did not begin until the late 19th century in the United States. Passion flower was used to treat nervous restlessness and gastrointestinal spasms. In short, the effects of passion flower were believed to be primarily on the nervous system, particularly for **anxiety** (page 30) due to mental worry and overwork.<sup>1</sup>

The effectiveness of passion flower as a treatment for anxiety has been confirmed in a double-blind study. In that study, 45 drops per day of an extract of passion flower taken for four weeks was as effective as 30 mg per day of oxazepam (Serax), a medication used for anxiety.<sup>2</sup>

### Active constituents

For many years, plant researchers believed that a group of harman alkaloids were the active constituents in passion flower. Recent studies, however, have pointed to

the **flavonoids** (page 516) in passion flower as the primary constituents responsible for its relaxing and anti-anxiety effects.<sup>3</sup> European herbal pharmacopoeias typically recommend passion flower products containing no less than 0.8% total flavonoids. The European literature involving passion flower recommends it primarily for the treatment of mild to moderate **anxiety** (page 30). In this context, it is often combined with **valerian** (page 756), **lemon balm** (page 701), and other herbs with sedative properties.

### How much is usually taken?

The recommended intake of the dried herb is 4–8 grams per day.<sup>4</sup> To make a tea, 0.5 to 2.5 grams of the herb can be steeped with boiling water for ten to fifteen minutes and drunk two to three times per day. Alternatively, 5–10 ml of passion flower tincture can be taken three to four times per day.

### Are there any side effects or interactions?

Used in the amounts listed above, passion flower is generally safe and has not been found to adversely interact with other sedative drugs. Some practitioners suggest not using passion flower with MAO-inhibiting antidepressant drugs because of concerns that they may interact with the harman alkaloids in passion flower.<sup>5</sup> However, this interaction is theoretical and has not been reported in the medical literature. A single case has been reported of a 34-year-old female who developed severe nausea, vomiting, drowsiness, and heart symptoms following self-administration of passion flower. It is not known for certain if passion flower caused her symptoms.<sup>6</sup> Passion flower has not been proven to be safe during **pregnancy** (page 363) and **breast-feeding** (page 74).

## PAU D'ARCO

**Common names:** Lapacho, taheebo

**Botanical names:** *Tabebuia avellanedae*, *Tabebuia impetiginosa*

### Parts used and where grown

Various related species of pau d'arco trees grow in rain forests throughout Latin America. The bark is used for medical purposes.

**Pau d'arco has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Infection</b> (page 265) <b>Prostatitis</b> (page 377)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Native peoples in Central and South America reportedly use pau d'arco bark to treat **cancer** (page 87), **lupus** (page 421), infectious diseases, **wounds** (page 319), and many other health conditions.<sup>1</sup> Caribbean folk healers use the leaf of this tree in addition to the bark for the treatment of backache, toothache, sexually transmitted diseases, and as an aphrodisiac.

#### **Active constituents**

Lapachol and beta-lapachone (known collectively as naphthaquinones) are two primary active compounds in pau d'arco. According to laboratory tests, both have anti-fungal properties as potent as ketoconazole, a common antifungal drug.<sup>2</sup> However, amounts of these constituents needed to exert an antifungal effect may be toxic to humans. Although these compounds also have anticancer properties according to test tube studies, the effective amount for this effect may also be toxic.<sup>3, 4</sup> Therefore, pau d'arco cannot currently be recommended as a treatment for cancer.

#### **How much is usually taken?**

A traditional recommendation is 2–3 teaspoons (10–15 grams) of the inner bark simmered in a pint (500 ml) of water for fifteen minutes three times per day.<sup>5</sup> However, the naphthaquinones believed to give pau d'arco its major effects are very poorly extracted in water, so teas are not usually recommended in modern herbal medicine.<sup>6</sup> Capsules or tablets providing 500–600 mg of powdered bark can be taken three times per day. A tincture,  $\frac{1}{8}$ – $\frac{1}{4}$  teaspoon (0.5–1 ml) three times per day, can also be used.

#### **Are there any side effects or interactions?**

High amounts (several grams daily over several days) of lapachol can cause uncontrolled bleeding, nausea, and vomiting.<sup>7</sup> Use of the whole bark is typically safer than isolated lapachol—side effects have included

nausea and gastrointestinal upset.<sup>8</sup> **Pregnant** (page 363) or breast-feeding women should avoid use of pau d'arco.

One case report exists of a 28-year-old man who died of liver failure after taking unspecified amounts of pau d'arco, scullcap, and zinc.<sup>9</sup> It appears likely that this may have been a case of adulteration of scullcap with germander.<sup>10</sup>

## **PENNYROYAL**

**Common names:** European pennyroyal, American pennyroyal, fleabane

**Botanical names:** *Hedeoma pulegoides*, *Mentha pulegium*

#### **Parts used and where grown**

Two similar plants go by the name pennyroyal, one native to Europe (and therefore called European pennyroyal) and one native to North America (and therefore called American pennyroyal). Both are members of the mint family (*Lamiaceae*) and grow in temperate regions of Europe and the Americas. The flowering tops are used as medicine, but the internal use of the volatile oil should be strictly avoided.

**Pennyroyal has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Anxiety</b> (page 30) <b>Cough</b> (page 139) Insect repellant

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Since the time of the ancient Greeks, pennyroyal was considered a useful insect repellant, reflected in modern times by the common name fleabane.<sup>1</sup> The Latin names of both plants also reflect this insect-repelling power—*pulegoides* and *pulegium* both derive from the Latin word for flea. It was also believed to stimulate menstruation. Various folk herb traditions have employed American or European pennyroyal to help relieve **coughs** (page 139), **upset stomachs** (page 260), and **anxiety** (page 30).<sup>2</sup>

## Active constituents

Like all mint family plants, pennyroyal owes much of its medicinal activity to the presence of a volatile oil. The primary component of this oil is known as pulegone. Pulegone is converted to menthofuran by the body. If large enough amounts of pulegone are consumed, the amount of menthofuran produced can seriously damage the liver and nervous system.<sup>3</sup> Smaller amounts of the volatile oil contained in the whole plant appear to have mild, smooth, muscle-relaxing effects that might help explain the historical use of pennyroyal for **indigestion** (page 260), stomach cramps, and **cough** (page 139).<sup>4</sup> No modern clinical trials have been completed to support these indications, and other herbs with soothing effects on the gastrointestinal tract, such as **chamomile** (page 656) and **peppermint** (page 726), have a much greater history of safety than pennyroyal.

## How much is usually taken?

For adults (excluding **pregnant** [page 363] or nursing women, children, and people with liver or kidney disease), a tea of pennyroyal can be prepared by putting 1–2 teaspoons (5–10 grams) of the herb in 1 cup (250 ml) of boiling water and allowing it to steep for 10–15 minutes.<sup>5</sup> Up to 2 cups (500 ml) per day can be drunk. Pennyroyal tincture can be mixed with a skin cream and applied topically to repel insects, though it is unknown whether this is effective due to a lack of scientific study. The tincture and volatile oil are not recommended for internal use.

## Are there any side effects or interactions?

Used internally in the amounts stated above, pennyroyal is generally safe, though an occasional person may experience intestinal upset or temporary dizziness.<sup>6</sup> Pulegone and its toxic metabolites, particularly menthofuran, damage the liver and nerves if taken in sufficiently large quantities.<sup>7</sup> If used during **pregnancy** (page 363), pennyroyal may cause fetal death by liver and brain damage as well as promote uterine contractions to expel the fetus.<sup>8</sup> Therefore pregnant or nursing women should absolutely avoid pennyroyal in any form. The traditional use of the herb to induce an abortion has led to many reports of nervous system toxicity in pregnant women. Internal ingestion of pennyroyal volatile oil should be avoided by everyone. People with liver failure or kidney failure, and all children, should avoid pennyroyal. Signs and symptoms of pennyroyal toxicity include severe stomach pain, dizziness, seizures, vomiting, difficulty

walking, and coma. Since 1905, 18 cases of injury (with complete recovery in every case) and four deaths related to pennyroyal have been reported in the medical literature.<sup>9</sup> The majority of acute poisonings and deaths reported with pennyroyal have been in cases of women using the oil attempting to induce an abortion.

## PEONY

**Common names:** Moutan (mu dan), red peony (chi shao), white peony (bai shao)

**Botanical names:** *Paeonia suffruticosa*, *Paeonia lactiflora*, *Paeonia veitchii*

## Parts used and where grown

Three similar plants are all called peony, and different parts are used in some cases. The bark of the root of *Paeonia suffruticosa* is called moutan or mu dan in China, where it naturally grows. Red peony root comes from wild harvested *Paeonia lactiflora* or *Paeonia veitchii*. White peony root comes from cultivated *Paeonia lactiflora*. The bark, red peony root, and white peony root all have somewhat different properties. Dried versus charred roots also have different properties. The color indicated does not refer to flower color. An important formula used in Chinese and Japanese herbal medicine called shakuyaku-kanzo-to contains white peony root and **licorice** (page 702) root. The roots and flowers of *Paeonia officinalis* have been used in European herbal medicine. However, the German Commission E did not approve this plant for medicinal use.<sup>1</sup>

**Peony has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Chronic viral hepatitis</b> (page 220) <b>Liver cirrhosis</b> (page 290) (shakuyaku-kanzo-to formula) Muscle cramps (shakuyaku-kanzo-to formula)
★☆☆	<b>Atherosclerosis</b> (page 38) (red peony root) <b>Dysmenorrhea</b> (page 171) (painful menses) Fever (moutan bark) Polycystic ovary syndrome (shakuyaku-kanzo-to) <b>Premenstrual syndrome</b> (page 368) (PMS)

### Historical or traditional use (may or may not be supported by scientific studies)

Peony is an ancient, traditional Chinese herbal medicine.<sup>2</sup> The plant was and is extensively cultivated as an ornamental plant as well. Peony is named for the mythical Greek figure Paeon, who was said to be a student of Aesculapius, the great physician.<sup>3</sup> Paeon used the peony plant (various species also grow in Europe) to heal a wound for the god Pluto. This earned Aesculapius's jealous wrath, but Pluto saved Paeon from death by turning him into a peony plant.

Bai shao or white peony was considered useful for **hypertension** (page 246), chest pain, muscle cramping and spasms, and fever.<sup>4</sup> It was an important remedy for female reproductive conditions ranging from **dysmenorrhea** (page 171) (painful menstruation) to irregular menses.<sup>5</sup> Chi shao or red peony was used for bleeding or lack of blood movement, depending on how it was prepared.<sup>6</sup> Moutan was also considered helpful for problems characterized by bleeding, such as nosebleeds, bleeding wounds, or menorrhagia (excessive menstrual bleeding).<sup>7</sup>

### Active constituents

Peony contains a unique glycoside called paeoniflorin. Proanthocyanidins, flavonoids, tannins, polysaccharides, and paeoniflorin are all considered to contribute to the medicinal activity of various forms of peony. Paeoniflorin's major effect seems to be to calm nerves and alleviate spasm. One study has confirmed the efficacy of shakuyaku-kanzo-to (formula with peony and **licorice** [page 702]) for relieving muscle cramps due to **cirrhosis of the liver** (page 290), **diabetes** (page 152), and dialysis.<sup>8</sup> Shakuyaku-kanzo-to is approved by the Japanese Ministry of Health and Welfare for treatment of muscle cramps. Another Japanese formulation known as toki-shakuyaku-san combines peony root with **dong quai** (page 668) and four other herbs and has been found to effectively reduce symptoms of cramping and pain associated with **dysmenorrhea** (page 171) (painful menses).<sup>9</sup>

Paeoniflorin and peony extracts also enhance mental function in animal studies,<sup>10</sup> suggesting a potential benefit for dementia. Human studies have not yet been conducted to confirm this theory.

Red peony root and moutan bark have both shown **antioxidant** (page 467) activity in test tubes, likely due to the presence of paeoniflorin, proanthocyanidins, and

flavonoids.<sup>11</sup> Polysaccharides found in peony bark and root have shown an ability to stimulate immune cells in the test tube.<sup>12, 13</sup>

Animal studies have found that red peony root, alone or in combination with other Chinese herbs, could help prevent liver damage due to various chemical toxins.<sup>14</sup> A crude extract of red peony root was shown in a small, preliminary trial to reduce liver fibrosis in some patients with **chronic viral hepatitis** (page 220).<sup>15</sup> Other case studies published in Chinese have found red peony root helpful for people with viral hepatitis.<sup>16</sup>

Crude red peony root extracts and combinations of these extracts with other Chinese herbs inhibit platelet aggregation, thrombosis, and excessive clotting in the test tube and in animals.<sup>17, 18</sup> A rabbit study found that peony was effective at lowering **cholesterol** (page 223) levels in the aorta.<sup>19</sup> A preliminary human study confirmed that peony could inhibit platelet clumping.<sup>20</sup> This suggests that peony might be helpful for prevention of **atherosclerosis** (page 38). However, clinical studies are needed to confirm this effect.

One uncontrolled clinical trial reported that moutan bark could significantly lower blood pressure in people with **hypertension** (page 246).<sup>21</sup>

Peony shows some weak estrogen-like effects, acting like a very weak anti-estrogen, particularly as part of the formula shakuyaku-kanzo-to. In a preliminary study, this formula was shown to improve fertility in women affected by polycystic ovary syndrome.<sup>22</sup>

### How much is usually taken?

White peony capsules are used in the amount of 1.5 to 4 grams three times per day. Red peony and moutan capsules are used in the amount of 1 to 3 grams three times per day.<sup>23</sup> Capsules of shakuyaku-kanzo-to formula are used in the amount of 2.5 grams three times per day.<sup>24</sup>

### Are there any side effects or interactions?

If used in the amounts listed above, peony is not associated with side effects. It is not known whether peony is safe for use during pregnancy, though there is an uncontrolled study showing it could safely be used to lower blood pressure in pregnant women.<sup>25</sup>

Shakuyaku-kanzo-to should be taken only while under the care of a healthcare professional trained in herbal medicine.

## PEPPERMINT

**Botanical name:** *Mentha piperita*

### Parts used and where grown

Peppermint is a hybrid of water mint and spearmint and was first cultivated near London in 1750. Peppermint is now cultivated widely, particularly in the U.S. and Europe. The two main cultivated forms are the black mint, which has violet-colored leaves and stems and a relatively high oil content, and the white mint, which has pure green leaves and a milder taste. The leaves are used medicinally.

**Peppermint has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Irritable bowel syndrome</b> (page 280) (combination with <b>caraway</b> [page 651] oil)
★★☆	<b>Gingivitis (periodontal disease)</b> (page 203) <b>Indigestion</b> (page 260) <b>Irritable bowel syndrome</b> (page 280) <b>Shingles</b> (page 401) (postherpetic neuralgia) (topical) <b>Tension headache</b> (page 430) (topical)
★☆☆	<b>Chronic candidiasis</b> (page 109) <b>Colic</b> (page 121) <b>Common cold</b> (page 129) <b>Gallstones</b> (page 193) <b>Low back pain</b> (page 293) (topical)

### Historical or traditional use (may or may not be supported by scientific studies)

Recognized in the early 18th century, the historical use of peppermint is not dramatically different than its use in modern herbal medicine. Classified as a carminative herb, peppermint has been used as a general digestive aid and employed in the treatment of **indigestion** (page 260) and intestinal **colic** (page 121) by herbalists.<sup>1</sup>

### Active constituents

Peppermint leaves yield approximately 0.1–1.0% volatile oil which is composed primarily of menthol (29–48%) and menthone (20–31%).<sup>2</sup> Peppermint oil is classified as a carminative (prevents and relieves intestinal gas).<sup>3</sup> It may also relieve spasms in the intestinal tract. Peppermint oil or peppermint tea is often used to treat gas and indigestion.

Three double-blind trials found that enteric-coated peppermint oil reduced the pain associated with intestinal spasms, commonly experienced in **irritable bowel syndrome** (page 280) (IBS).<sup>4,5,6</sup> However, another trial found no effect of peppermint on IBS.<sup>7</sup> A double-blind trial found that an enteric-coated combination of peppermint and **caraway** (page 651) oils was superior to a placebo for people with gastrointestinal complaints including IBS.<sup>8</sup> A combination of peppermint, caraway seeds, and two other carminative herbs (**fennel** [page 676] seeds and **wormwood** [page 762]) was reported to be effective for gastrointestinal complaints including IBS in another double-blind study.<sup>9</sup>

A tea of peppermint is a traditional therapy for **colic** (page 121) in infants but has never been investigated in a human trial. Peppermint should be used cautiously in infants (see side effects below).

Peppermint oil's relaxing action also extends to topical use. When applied topically, it acts as an analgesic and reduces pain.<sup>10</sup> A trial of topical peppermint oil applied to the temples of healthy volunteers (with or without **eucalyptus** [page 673] oil) found that peppermint oil had a muscle-relaxing action and it decreased tension.<sup>11</sup> Topical peppermint oil alone reduced pain in people with tension headaches as well.

### How much is usually taken?

For internal use, a tea can be made by pouring 1 cup (250 ml) of boiling water over 1 heaped teaspoon (5 grams) of the dried leaves and steeping for five to ten minutes. Three to four cups (750–1000 ml) daily between meals can be taken to relieve stomach and gastrointestinal complaints.<sup>12</sup> Peppermint leaf tablets and capsules, 3–6 grams per day, can be taken. For treatment of **irritable bowel syndrome** (page 280), 1–2 enteric-coated capsules containing 0.2 ml of peppermint oil taken two to three times per day is recommended.

For headaches, a combination of peppermint oil and eucalyptus oil diluted with base oil can be applied to the temples at the onset of the headache and every hour after that or until symptom relief is noted.

### Are there any side effects or interactions?

Peppermint tea is generally considered safe for regular consumption. Peppermint oil can cause burning and gastrointestinal upset in some people.<sup>13</sup> It should be avoided by people with chronic **heartburn** (page 260), severe liver damage, inflammation of the gallbladder, or obstruction of bile ducts.<sup>14</sup> People with **gallstones**

(page 193) should consult a physician before using peppermint leaf or peppermint oil. Some people using enteric-coated peppermint capsules may experience a burning sensation in the rectum. Rare allergic reactions have been reported with topical use of peppermint oil. Peppermint oil should not be applied to the face—in particular, the nose—of children and infants. Peppermint tea should be used with caution in infants and young children, as they may choke in reaction to the strong menthol. **Chamomile** (page 656) is usually a better choice for this group for treating **colic** (page 121) and mild gastrointestinal complaints.

## PERIWINKLE

**Common name:** Lesser periwinkle

**Botanical name:** *Vinca minor*

### Parts used and where grown

The flower and leaf of lesser periwinkle are used medicinally. Periwinkle is an evergreen shrub that grows in Europe, northwestern Africa, central Asia, and some parts of North America.

**Periwinkle has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Alzheimer's disease</b> (page 19)
★★★	<b>Canker sores</b> (page 90) Dementia (vascular) Dialysis <b>Diarrhea</b> (page 163) <b>Glaucoma</b> (page 205) Hearing loss (presbycusis) <b>Menorrhagia</b> (page 314) <b>Stroke</b> (page 419) <b>Tinnitus</b> (page 430)

### Historical or traditional use (may or may not be supported by scientific studies)

Periwinkle has likely been used for medicine for a long time; its Latin name, *Vinca*, is derived from the Latin word *vincere*, meaning “to overcome.” European herbalists have used periwinkle for headaches, vertigo, and poor memory since medieval times.<sup>1</sup> It was also

considered a helpful remedy for conditions with a watery or bloody discharge such as **diarrhea** (page 163), bleeding gums, or **menorrhagia** (page 314).<sup>2</sup>

### Active constituents

There are two classes of active compounds in lesser periwinkle—alkaloids and tannins. The major alkaloid is known as vincamine. A closely related semisynthetic derivative of vincamine most widely used as medicine is known as ethyl-apovincamine or vinpocetine. It has vasodilating, blood thinning, and memory-enhancing actions. It has been shown in double-blind studies to help alleviate a type of dementia known as vascular dementia, in which the arteries supplying blood to the brain develop **atherosclerotic** (page 38) plaques.<sup>3, 4, 5</sup> A double-blind study found that vincamine can help people with **Alzheimer's disease** (page 19),<sup>6</sup> while one open study did not.<sup>7</sup> Vinpocetine has also been found to prevent the decline in short-term memory induced by the anti-anxiety benzodiazepine drug flunitrazepam in one preliminary study.<sup>8</sup> Further study is needed to determine whether vinpocetine would be a helpful adjunct to use of benzodiazepines.

One double-blind study found that high amounts of vinpocetine (60 mg per day) could have a beneficial effect on hearing loss due to aging (presbycusis).<sup>9</sup> A preliminary study concluded that supplementation with ethyl-apovincamine (a vinca alkaloid) may reduce symptoms of **tinnitus** (page 430) (ringing in the ears) due to impaired blood flow to the inner ear.<sup>10</sup> One review of the use of vinpocetine in people who have suffered **strokes** (page 419) found that the only double-blind study did not show efficacy,<sup>11</sup> though previous uncontrolled studies have suggested there might be a benefit.<sup>12, 13</sup>

Vinpocetine tends to act as a calcium-chelating agent. One uncontrolled study found that use of vinpocetine for 3 to 12 months could eliminate calcium buildup in people undergoing dialysis.<sup>14</sup> Further research is needed to determine whether this could be helpful in other conditions associated with excess calcium, or whether vinpocetine might interfere with calcium's beneficial actions.

One double-blind and one preliminary study have found that brovincamine, a compound closely related to vinpocetine, was helpful in people with chronic **glaucoma** (page 205).<sup>15, 16</sup> Until studies have been conducted using actual vinpocetine, it is unknown whether it would be as effective as brovincamine.

Crude periwinkle also contains tannins. These make it a mild astringent. It may relieve pain from canker sores or sore throats, according to traditional use. Clinical trials have not been conducted to confirm this.

#### **How much is usually taken?**

The amount of vincristine used in most studies is 15 mg one to three times per day.<sup>17</sup> Vincristine should be taken with food, as it has been shown to be better absorbed with meals than when taken away from meals.<sup>18</sup> It may take three to six weeks before any improvement is noted.<sup>19</sup>

A tincture can be taken in the amount of 1 to 2 ml three times per day.<sup>20</sup> A tea can be made by infusing 1 teaspoon of herb into a cup of water for 10 to 15 minutes; three cups per day should be drunk.<sup>21</sup> Research has not been conducted to determine whether a tincture or a tea provides enough periwinkle compounds to have the same effects as vincristine.

#### **Are there any side effects or interactions?**

Vincristine has been reported to occasionally cause an upset stomach, flushing of the skin, and a skin rash;<sup>22</sup> these effects are mild and rarely cause anyone to stop taking it. The whole periwinkle herb may also cause minor stomach upset. This may be remedied by taking the herb with food. Neither vincristine nor periwinkle should be taken during pregnancy or breast-feeding until more information is available. The Commission E of the German government states that some animal studies suggest periwinkle could suppress the immune system.<sup>23</sup> This problem has not been observed to date in studies involving vincristine.

**Phyllanthus has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Hepatitis</b> (page 220)
★☆☆	<b>Pain</b> (page 338)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Phyllanthus has been used in Ayurvedic medicine for over 2,000 years and has a wide number of traditional uses including internal use for jaundice, gonorrhea, frequent menstruation, and **diabetes** (page 152) and topical use as a poultice for skin ulcers, sores, swelling, and itchiness. The young shoots of the plant are administered in the form of an infusion for the treatment of chronic dysentery.<sup>2</sup>

#### **Active constituents**

Phyllanthus primarily contains lignans (e.g., phyllanthine and hypophyllanthine), alkaloids, and **flavonoids** (page 516) (e.g., **quercetin** [page 580]).

Phyllanthus blocks DNA polymerase, the enzyme needed for the **hepatitis** (page 220) B virus to reproduce. In one study, 59% of those infected with chronic viral hepatitis B lost one of the major blood markers of HBV infection (e.g., hepatitis B surface antigen) after using 900 mg of phyllanthus per day for 30 days.<sup>3</sup> While clinical trials on the effectiveness of phyllanthus for HBV have been mixed, the species *P. urinaria* and *P. niruri* seem to work better than *P. amarus*.<sup>4</sup> Clinical trials with hepatitis B patients have used 900–2,700 mg of phyllanthus per day.

#### **How much is usually taken?**

Research has used the powdered form of phyllanthus ranging from 900–2,700 mg per day for three months.<sup>5</sup>

#### **Are there any side effects or interactions?**

No side effects have been reported using phyllanthus as recommended in the amounts above.

## **PICRORHIZA**

**Common names:** Kutki, katuka

**Botanical name:** *Picrorhiza kurroa*

### Parts used and where grown

The herb originated in and continues to grow primarily in the Himalayan mountains. The rhizomes or underground stems of picrorhiza are used.

### Picrorhiza has been used in connection with the following conditions (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Asthma</b> (page 32) <b>Vitiligo</b> (page 443)
★☆☆	<b>Hepatitis (acute viral)</b> (page 220) <b>Indigestion</b> (page 260) <b>Infection</b> (page 265) <b>Rheumatoid arthritis</b> (page 387)

### Historical or traditional use (may or may not be supported by scientific studies)

The bitter rhizomes of picrorhiza have been used for thousands of years in India to treat people with **indigestion** (page 260).<sup>1</sup> It is also used to treat people with **constipation** (page 137) due to insufficient digestive secretion and for fever due to all manner of **infections** (page 265).<sup>2</sup>

### Active constituents

The major constituents in picrorhiza are the glycosides picroside I, kutkoside, androsin, and apocynin. They have been shown in animal studies to be antiallergic, to inhibit platelet-activating factor (an important pro-inflammatory molecule),<sup>3</sup> and to decrease joint inflammation.<sup>4</sup> According to test tube and animal studies, picrorhiza has antioxidant actions, particularly in the liver.<sup>5, 6</sup> Picroliv (a commercial mixture containing picroside I and kutkoside) has been shown to have an immunostimulating effect in hamsters, helping to prevent infections.<sup>7</sup> Picrorhiza increases bile production in the liver, according to rat studies.<sup>8</sup> It has also been shown to protect animals from damage by several potent liver toxins, offering protection as good as or better than silymarin (the **flavonoids** [page 516] found in **milk thistle** [page 710]).<sup>9, 10</sup> However, it does not have the amount of human research as silymarin. Picrorhiza has also shown to reduce formation of liver **cancer** (page 87) due to chemical exposures in animal studies.<sup>11</sup>

Human studies on this plant are not prolific. A series of cases of acute viral **hepatitis** (page 220) in India were

reportedly treated successfully by a combination of picrorhiza with a variety of minerals.<sup>12</sup> A number of similar reports have appeared in Indian literature over the years. No double-blind clinical trials have yet been published, however.

Two preliminary trials suggest that picrorhiza may improve breathing in asthma patients and reduce the severity of **asthma** (page 32).<sup>13, 14</sup> Although, a follow-up double-blind trial did not confirm these earlier trials.<sup>15</sup>

A preliminary trial conducted in India found a small benefit for people with arthritis (primarily **rheumatoid arthritis** [page 387]).<sup>16</sup>

Picrorhiza in combination with the drug methoxsalen was found in a preliminary trial to hasten recovery in people with **vitiligo** (page 443) faster than those receiving methoxsalen and sun exposure alone.<sup>17</sup>

### How much is usually taken?

Between 400 and 1,500 mg of powdered, encapsulated picrorhiza per day has been recommended. One author considers this equivalent to the use of 1–2 ml of fluid extract twice per day.<sup>18</sup> Picrorhiza tastes quite bitter. Combining with **ginger** (page 680) root powder capsules or taking as tea can improve palatability.

### Are there any side effects or interactions?

Loose stools and **colic** (page 121) have been reported when unprepared picrorhiza rhizomes are used as medicine. However, extracts in alcohol have shown much less tendency to cause such effects.<sup>19</sup> No other adverse effects have been reported with picrorhiza. Although the use of the herb is not discouraged in India during **pregnancy** (page 363) and breast-feeding, there is little information to determine the safety of the herb during these times.

## PLANTAIN

**Common names:** Broadleaf plantain, lanceleaf plantain, ribwort

**Botanical names:** *Plantago lanceolata*, *Plantago major*

### Parts used and where grown

These green, weedy plants are native to Europe and Asia, but now grow practically anywhere in the world where there is sufficient water. Plantain should not be

confused with the banana-like vegetable of the same name. The leaves of plantain are primarily used as medicine. The seeds of plantain can also be used medicinally, having mild laxative effects similar to the seeds of **psyllium** (page 732), a close relative of plantain.

**Plantain has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Chronic bronchitis</b> (page 80)
★★★	<b>Burns</b> (page 85) (topical)
	<b>Cough</b> (page 139)
	Dermatitis (topical)
	Insect bites or stings (topical)
	<b>Peptic ulcer</b> (page 349)
	<b>Urinary tract infections</b> (page 436)
	<b>Wounds</b> (page 319) (topical)

**Historical or traditional use (may or may not be supported by scientific studies)**

Plantain has long been considered by herbalists to be a useful remedy for **cough** (page 139), **wounds** (page 319), inflamed skin or dermatitis, and insect bites.<sup>1</sup> Bruised or crushed leaves have been applied topically to treat insect bites and stings, **eczema** (page 177), and small wounds or cuts. It was considered by herbalists to be a gentle, soothing expectorant, and additionally to have a mild astringent effect said to help remedy **hemorrhoids** (page 219) or **bladder infections** (page 436) with mild amounts of blood in the urine.<sup>2</sup>

**Active constituents**

The major constituents in plantain are mucilage, iridoid glycosides (particularly aucubin), and tannins. Together these constituents are thought to give plantain mild anti-inflammatory, antimicrobial, antihemorrhagic, and expectorant actions.<sup>3,4</sup> Plantain is approved by the German Commission E for internal use to ease **coughs** (page 139) and mucous membrane irritation associated with upper respiratory tract infections as well as topical use for skin inflammations.<sup>5</sup> Two Bulgarian clinical trials have suggested that plantain may be effective in the treatment of chronic **bronchitis** (page 80).<sup>6,7</sup> Insufficient details were provided in these reports to determine the quality of the trials or their findings. Although plantain was thought to possess diuretic

properties, one double-blind trial failed to show any diuretic effect for this plant.<sup>8</sup> A preliminary trial found that topical use of a plantain ointment (10% ground plantain in a base of petroleum jelly) was helpful as part of the treatment of people with impetigo and ecthyma, two inflammatory skin disorders.<sup>9</sup> Insufficient details were provided in this report, however, to determine the quality of the study or its findings.

**How much is usually taken?**

The German Commission E recommends using  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–3 grams) of the leaf daily in the form of tea made by steeping the herb in 1 cup (250 ml) of hot water for 10–15 minutes (making three cups (750 ml) per day).<sup>10</sup> The fresh leaves can be applied directly three or four times per day to **minor injuries** (page 319), dermatitis, and insect stings.<sup>11</sup> Syrups or tinctures, approximately  $\frac{1}{2}$  teaspoon (2–3 ml) three times per day, can also be used, particularly to treat a **cough** (page 139).<sup>12</sup> Finally,  $\frac{1}{2}$ – $\frac{1}{4}$  teaspoons (2–6 grams) of the fresh plant can be juiced and taken in three evenly divided oral administrations throughout the day.<sup>13</sup>

**Are there any side effects or interactions?**

Plantain is not associated with any common side effects and is thought to be safe for children.<sup>14</sup> There is no information available about its use by **pregnant** (page 363) or nursing women, though topical application appears to be safe. Adulteration of plantain with digitalis leading to dangerous side effects has been reported in Switzerland and the United States.<sup>15</sup> Although rare, it points to the need for consumers to purchase herbs from companies that carefully test their herbal products for adulteration.

## PLEURISY ROOT

**Botanical name:** *Asclepias tuberosa*

**Parts used and where grown**

As its common name indicates, the root of pleurisy root is used as medicine. This brilliant-orange-flowered herb is native to and continues to grow primarily in the southwestern and midwestern United States. Many plants similar to pleurisy root are known as milkweeds because they produce a milky sap—something pleurisy root does not do.

**Pleurisy root has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Bronchitis</b> (page 80) Fever Pleurisy Pneumonia

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Pleurisy root was used by Native American tribes both internally as a remedy for pulmonary infections and topically to treat wounds.<sup>1</sup> The Eclectic physicians seized upon these ideas and continued to use the plant primarily for lung problems such as pleurisy and pneumonia. It was also used as a diaphoretic (a substance that causes sweating) for all manner of **infections** (page 265).<sup>2</sup> Pleurisy root was an official medicine in the United States Pharmacopoeia from 1820 to 1905.<sup>3</sup>

#### **Active constituents**

Insufficient work has been done to identify the active constituents in pleurisy root or its medicinal actions. No human studies have been conducted to determine whether it is effective for any indication. It is still used by herbalists and some physicians trained in herbal medicine as a diaphoretic (promotes sweating), and for lung infections and conditions of the pleura that lines the lungs.<sup>4</sup>

#### **How much is usually taken?**

A pleurisy root tea can be made by lightly simmering one teaspoon of the dried, chopped root in one pint of water for 10 to 15 minutes. One cup of this tea can be drunk twice per day.<sup>5</sup> Alternately, 1 to 2 ml of tincture of the fresh root can be used three times per day.<sup>6</sup>

#### **Are there any side effects or interactions?**

At the amounts recommended above, pleurisy root generally has no adverse effects. Excessive intake (1 tablespoon or more of the root at one time) can cause intestinal cramping, nausea, vomiting, and **diarrhea** (page 163).<sup>7</sup> Pleurisy root should be avoided by pregnant women as it may stimulate uterine contractions.<sup>8</sup>

## **PRICKLY ASH**

**Common names:** Toothache tree, American prickly ash

**Botanical names:** *Zanthoxylum clava-herculis*, *Zanthoxylum americanum*

#### **Parts used and where grown**

The bark and sometimes the berries of these two American trees are used as medicine. There are many other trees in this genus that grow on other continents, including Chinese prickly ash (*Zanthoxylum bungeanum*), which grows in Asia.

#### **Prickly ash has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Indigestion</b> (page 260) Insufficient salivation Rheumatism Toothache

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Many eastern Native American tribes valued prickly ash as a remedy for **upset stomach** (page 260), **sore throats** (page 129), aching muscles, skin **infections** (page 265), to stimulate saliva flow, and various other conditions.<sup>1</sup> Eclectic physicians (doctors who recommended herbal medicines) in the United States at the end of the 19th century continued the traditional uses of prickly ash, primarily as a digestive aid, to strengthen the nervous system, and for cholera.<sup>2</sup> The bark was also widely used by herbalists to treat rheumatic conditions.<sup>3</sup> Prickly ash is also considered an alterative in traditional herbalism, meaning it enhances the body's ability to fight against and recover from all manner of difficulties.<sup>4</sup> Chinese prickly ash (*Zanthoxylum simulans*) is used for similar indications as its American relative as well as for killing **parasites** (page 343).<sup>5</sup>

#### **Active constituents**

Prickly ash bark contains alkaloids and a volatile oil. The fruit is rich in the volatile oil. Little research has been done specifically on the constituents or actions of American prickly ash. Preliminary Chinese trials have reportedly

found that oral use of Chinese prickly ash berries can alleviate pain due to **indigestion** (page 260), gallbladder disease, or ulcers, as well as eliminating **pinworms** (page 343).<sup>6</sup> Herculin, an alkamide in the plant, produces a localized numbing effect on the tongue when consumed.<sup>7</sup> Whether this explains the historical use of prickly ash for toothaches remains to be confirmed in clinical trials.

#### How much is usually taken?

A tea of prickly ash is made by simmering 1–2 teaspoons (5–10 grams) of the bark for 10–15 minutes. Three cups (750 ml) per day are recommended.<sup>8</sup> Alternatively, a tincture,  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (2–4 ml) three times per day, may also be used.<sup>9</sup> Prickly ash is best taken just before meals. Traditionally, the bark was chewed to relieve tooth pain.<sup>10</sup>

#### Are there any side effects or interactions?

There are no known side effects from using the amounts of prickly ash noted above. Since it stimulates digestive function, prickly ash should best be avoided in conditions such as **ulcerative colitis** (page 433), **peptic ulcer disease** (page 349), or **gastroesophageal reflux** (page 198). Some herbal experts suggest that prickly ash be avoided by **pregnant** (page 363) women because it may stimulate menstruation and increase risk of a miscarriage.<sup>11</sup>

## PSYLLIUM

**Common names:** Flea seed, ispaghula, spogel

**Botanical names:** *Plantago ovata*, *Plantago ispaghula*

#### Parts used and where grown

Psyllium is native to Iran and India and is currently cultivated in these countries. The seeds are primarily used in traditional herbal medicine. Psyllium seed husks are mainly used to treat constipation.

**Psyllium has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Constipation</b> (page 139) <b>Diabetes</b> (page 152) <b>Diverticular disease</b> (page 168) <b>High cholesterol</b> (page 223) <b>Irritable bowel syndrome</b> (page 280)

★★☆

**Atherosclerosis** (page 38)

**Diarrhea** (page 163)

**Hemorrhoids** (page 219)

**High triglycerides** (page 238)

**Ulcerative colitis** (page 433) (to maintain remission)

★★☆

**Parkinson's disease** (page 345) (for constipation)

**Weight loss and obesity** (page 446)

#### Historical or traditional use (may or may not be supported by scientific studies)

In addition to its traditional and current use for **constipation** (page 137), psyllium was also used topically by herbalists to treat skin irritations, including poison ivy reactions and insect bites and stings. It has also been used in traditional herbal systems of China and India to treat **diarrhea** (page 163), **hemorrhoids** (page 219), bladder problems, and **high blood pressure** (page 246).

#### Active constituents

Psyllium is a bulk-forming laxative and is high in both **fiber** (page 512) and mucilage. Psyllium seeds contain 10–30% mucilage. The laxative properties of psyllium are due to the swelling of the husk when it comes in contact with water. This forms a gelatinous mass that keeps feces hydrated and soft, provided it is taken with sufficient water. The resulting bulk stimulates a reflex contraction of the walls of the bowel, followed by emptying.<sup>1</sup>

Psyllium is a common ingredient in over-the-counter bulk laxative products. One preliminary trial found that psyllium seeds relieved **constipation** (page 137) when it was due to lifestyle factors (e.g., inadequate **fiber** [page 512], sedentary lifestyle), but not when an actual disease was the cause.<sup>2</sup> Numerous double-blind trials have found that supplementation with psyllium can lower total **cholesterol** (page 223) and LDL ("bad") cholesterol.<sup>3</sup> However, levels of HDL ("good") cholesterol are not affected by psyllium supplementation.<sup>4</sup> The cholesterol-lowering effect of psyllium has been reported in children,<sup>5</sup> as well as in adults.<sup>6</sup> Psyllium supplementation has also improved blood sugar levels in some people with **diabetes** (page 152).<sup>7, 8, 9</sup> The soluble fiber component of psyllium is believed to account for this effect.

In a double-blind trial, people with **ulcerative colitis** (page 433) had a reduction in symptoms such as bleeding and remained in remission longer when they took 20 grams of ground psyllium seeds twice daily with water compared to the use of the medication mesalamine alone.<sup>10</sup> Also, the combination of the two was slightly more effective than either alone.

### How much is usually taken?

The suggested intake of psyllium husks to treat constipation is 1 teaspoon (approximately 5 grams) three times per day. Alternatively, some references suggest taking 2–6 teaspoons (10–30 grams) of the whole seeds per day—typically taken in three even amounts throughout the day.<sup>11</sup> This is stirred into a large glass of water or juice and drunk immediately before it thickens.<sup>12</sup> It is best to follow label instructions on over-the-counter psyllium products for **constipation** (page 137). It is important to maintain a high water intake when using psyllium.

### Are there any side effects or interactions?

Using psyllium in recommended amounts is generally safe. People with chronic **constipation** (page 137) should seek the advice of a healthcare professional. Some people with **irritable bowel syndrome** (page 280) feel worse when taking psyllium and may do better with soluble fiber, such as in fruit. People with an obstruction of the bowel or people with **diabetes** (page 152) who have difficulty regulating their blood sugar should not use psyllium.<sup>13</sup> Side effects, such as allergic skin and respiratory reactions to psyllium dust, have largely been limited to people working in factories manufacturing psyllium products.

## PUMPKIN

**Botanical names:** *Cucurbita pepo*, *Cucurbita maxima*

### Parts used and where grown

Pumpkins and other squashes are native to North and Central America, but have since been cultivated around the world. The seeds are primarily used in herbal medicine. The yellow blossoms of pumpkins are also used as medicine in some native traditions.

**Pumpkin seeds have been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Benign prostatic hyperplasia (BPH)</b> (page 58)
★☆☆	<b>Depression</b> (page 145) <b>Kidney stone</b> (page 284) <b>Parasites</b> (page 343)

### Historical or traditional use (may or may not be supported by scientific studies)

(may or may not be supported by scientific studies): Native Americans used pumpkin flesh and seeds for food. Their use of the seeds for the treatment of intestinal infections eventually led the United States Pharmacopoeia to list pumpkin seeds as an official medicine for **parasite** (page 343) elimination from 1863 to 1936.<sup>1</sup> Native Americans also commonly used pumpkin seeds to treat a variety of kidney problems. The flowers were used topically to soothe **minor injuries** (page 319).<sup>2</sup> Eclectic physicians (doctors who recommended herbal medicine) at the end of the 19th century used pumpkin seeds to treat **urinary tract** (page 436) problems and **gastritis** (page 195), and to remove tapeworms and roundworms from the intestines.<sup>3</sup>

### Active constituents

Pumpkin seeds contain several major groups of active constituents: essential fatty acids, **amino acids** (page 465), phytosterols (e.g., beta-sitosterol) minerals, and vitamins. Other major constituents include mucilaginous carbohydrates and minerals.

Pumpkin seed oil has been used in combination with **saw palmetto** (page 743) in two double-blind trials to effectively reduce symptoms of **benign prostatic hyperplasia** (page 58) (BPH).<sup>4,5</sup> Only one open label trial evaluated the effectiveness of pumpkin seed oil alone for BPH.<sup>6</sup> Animal studies have shown that pumpkin seed extracts can improve the function of the bladder and urethra. This might partially account for BPH symptom relief.<sup>7</sup>

Curcurbitin is a constituent in pumpkin seeds that has shown anti-parasitic activity in the test tube.<sup>8</sup> Human trials conducted in China have shown pumpkin seeds to be helpful for people with acute schistosomiasis, a severe parasitic disease occurring primarily in

Asia and Africa that is transmitted through snails.<sup>9</sup> Preliminary human research conducted in China and Russia has shown pumpkin seeds may also help resolve tapeworm infestations.<sup>10, 11</sup> The assistance of a physician is required to help diagnose and treat any suspected intestinal **parasite** (page 343) infections.

Due to the purported L-tryptophan content of pumpkin seeds, they have been suggested to help remedy **depression** (page 145).<sup>12</sup> However, research is needed before pumpkin seeds can be considered for this purpose.

Two trials in Thailand have reportedly found that eating pumpkin seeds as a snack can help prevent the most common type of **kidney stone** (page 284).<sup>13, 14</sup> Pumpkin seeds appear to both reduce levels of substances that promote stone formation in the urine and increase levels of substances that inhibit stone formation. The active constituents of pumpkin seeds responsible for this action have not been identified.

#### **How much is usually taken?**

Pumpkin seed oil extracts standardized for fatty acid content have been used in BPH trials. Men with BPH have used 160 mg three times per day with meals.<sup>15</sup> Approximately 5–10 grams per day of pumpkin seeds may be needed for kidney stone prevention.<sup>16</sup> As a treatment for parasites, 200–400 grams are ground and taken with milk and honey, followed by castor oil two hours later. This treatment, however, should not be attempted unless under medical supervision.

#### **Are there any side effects or interactions?**

Pumpkin seeds may cause an upset stomach, but are otherwise extremely safe. There is no reason to believe pumpkin seeds should be avoided during **pregnancy** (page 363) or breast-feeding as they are commonly consumed as food during these times without any indication of harm.

## **PYGEUM**

**Botanical names:** *Prunus africana*, *Pygeum africanum*

#### **Parts used and where grown**

Pygeum is an evergreen tree found in the higher elevations of central and southern Africa. The bark is used medicinally. Wild pygeum is environmentally threatened and efforts are being made to grow pygeum on plantations and control harvesting in the wild.

**Pygeum has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Benign prostatic hyperplasia</b> (page 58) (BPH)
★☆☆	<b>Prostatitis</b> (page 377) (CBP, NBP)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

The powdered bark was used as a tea for relief of urinary disorders in African herbal medicine. European scientists were so impressed with reports of pygeum's actions, they began laboratory investigations into the active constituents in the bark. This led to the development of the modern lipophilic (fat-soluble) extract used today.

#### **Active constituents**

Chemical analysis and pharmacological studies indicate the lipophilic extract of pygeum bark has three categories of active constituents: 1) Phytosterols, including **beta-sitosterol** (page 471), have anti-inflammatory effects by interfering with the formation of hormone-like substances in the body (prostaglandins) that tend to accumulate in the prostate of men with **benign prostatic hyperplasia** (page 58) (BPH); 2) pentacyclic terpenes have an anti-edema (page 180), or decongesting, effect; 3) ferulic esters indirectly control testosterone activity in the prostate, which may reduce the risk of BPH.<sup>1</sup> While these effects have been shown in test tube studies, human studies are still needed to confirm these effects in the body. Pygeum alone has been shown in some double-blind trials to help men with BPH by improving urinary flow and other symptoms of BPH.<sup>2, 3</sup> It has also been used successfully in combination with **nettle** (page 714) root to treat BPH.<sup>4</sup> Long-term BPH studies (six months or greater) on pygeum are lacking, however.

#### **How much is usually taken?**

The accepted form of pygeum used in Europe for treatment of **BPH** (page 58) is a lipophilic extract standardized to 13% total sterols (typically calculated as beta-sitosterol).<sup>5</sup> Men with mild to moderate BPH sometimes take 50–100 mg two times per day. A double-blind trial found that 100 mg once daily was as effective as 50 mg twice per day.<sup>6</sup> Pygeum should be monitored over at least a six-month period to deter-

mine efficacy. Men with BPH who are using pygeum should be supervised by a doctor.

#### **Are there any side effects or interactions?**

Side effects from the lipophilic extract of pygeum are rare. In clinical trials, there were reports of mild gastrointestinal upset in some men.

## **RED CLOVER**

**Botanical name:** *Trifolium pratense*

#### **Parts used and where grown**

This plant grows in Europe and North America. The flowering tops are used in botanical medicine. Another plant, white clover, grows in similar areas. Both have white arrow-shaped patterns on their leaves.

**Red clover has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Menopause</b> (page 311) <b>Osteoporosis</b> (page 333)
★☆☆	<b>Cough</b> (page 139) <b>Eczema</b> (page 177)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Traditional Chinese Medicine and Western folk medicine used this plant as a diuretic, a **cough** (page 139) expectorant (an agent that promotes discharge of mucus from the respiratory passages), and an alterative.<sup>1</sup> Alternative plants were considered beneficial for chronic conditions, particularly those afflicting the skin.

#### **Active constituents**

Red clover is known as an alterative agent (i.e., one that produces gradual beneficial changes in the body, usually by improving nutrition; also known as a “blood cleanser”). It is a traditional remedy for **psoriasis** (page 379) and **eczema** (page 177). However, the mechanism of action and constituents responsible for red clover’s purported benefit in skin conditions are unknown. Modern research has revealed that red clover also contains high amounts of isoflavones, such as genistein, which have weak estrogen-like properties.<sup>2</sup> Modern re-

search has focused on a red clover extract high in isoflavones as a possible treatment for symptoms associated with **menopause** (page 311) and **cardiovascular health** (page 98) in menopausal women. In a double-blind study, administration of 80 mg of isoflavones per day from red clover reduced the frequency of hot flashes in postmenopausal women. The benefit was noticeable after 4 weeks of treatment and became more pronounced after a total of 12 weeks.<sup>3</sup> Another double-blind trial found that red clover improved cardiovascular function in menopausal women.<sup>4</sup> Various laboratory studies and one case report of a man with prostate cancer suggest red clover isoflavones may help prevent **cancer** (page 87).<sup>5, 6</sup> In another case study, use of red clover by a man with prostate cancer led to noticeable anticancer effects in his prostate after the cancer was surgically removed. Although the isoflavones in red clover may help prevent certain forms of cancer (e.g., **breast** [page 65] and **prostate** [page 371]), further studies are needed before red clover is recommended for cancer patients.

#### **How much is usually taken?**

Traditionally, red clover is taken as a tea, by adding 1 cup (250 ml) of boiling water to 2–3 teaspoons (10–15 grams) of dried flowers and steeping, covered, for ten to fifteen minutes.<sup>7</sup> Three cups (750 ml) can be drunk each day. Red clover can also be used in capsule or tablet form, equivalent to 2–4 grams of the dried flowers. Also,  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (2–4 ml) of tincture three times per day may be taken. Standardized extracts providing 40 mg isoflavones per day are available as well.<sup>8</sup>

#### **Are there any side effects or interactions?**

Non-fermented red clover is relatively safe. However, fermented red clover may cause bleeding and should be avoided. Red clover supplements should be avoided by **pregnant** (page 363) or breast-feeding women and their safety has not been established in young children and infants.

## **RED RASPBERRY**

**Botanical name:** *Rubus idaeus*

#### **Parts used and where grown**

Raspberry bushes are native to North America and are cultivated in Canada. Although most well known for its delicious berries, raspberry’s leaves are used in medicine.

**Red raspberry has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Common cold/sore throat</b> (page 129) <b>Diarrhea</b> (page 163) <b>Pregnancy and postpartum support</b> (page 363)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Raspberry leaves have been used by herbalists to treat **diarrhea** (page 163). In traditional herbalism and midwifery, red raspberry has been connected to female health, including **pregnancy** (page 363). It was considered a remedy for excessive menstrual flow (**menorrhagia** [page 314]) and as a “partus prepartor,” or an agent used during pregnancy to help prevent complications.<sup>1</sup>

#### **Active constituents**

Raspberry leaves are high in tannins and like its relative, **blackberry** (page 636), may relieve acute **diarrhea** (page 163).<sup>2</sup> The constituents that affect the smooth muscles, such as in the uterus, have not yet been clearly identified. The German Commission E monograph has concluded there is insufficient proof to recommend red raspberry in modern herbal medicine.<sup>3</sup>

#### **How much is usually taken?**

Traditionally, raspberry leaf tea is prepared by pouring 1 cup (250 ml) boiling water over 1–2 teaspoons (5–10 grams) of the herb and steeping for ten to fifteen minutes. Up to 6 cups (1500 ml) per day may be necessary for acute problems such as **diarrhea** (page 163) or sore throats due to a **cold** (page 129), while less (two to three cups [500–750 ml]) is used for preventive use during **pregnancy** (page 363). By itself, raspberry is usually not a sufficient treatment for diarrhea. Tincture,  $\frac{3}{4}$ –1 teaspoon (4–8 ml) three times per day, may also be taken.

#### **Are there any side effects or interactions?**

Raspberry leaf may cause mild loosening of stools and nausea. Otherwise, use of the herb appears to be safe.

## RED YEAST RICE

**Botanical name:** *Monascus purpureus*

#### **Parts used and where grown**

This substance, native to China, is a fermentation by-product of cooked non-glutinous rice on which red yeast has been grown.<sup>1</sup> The dried, powdered red yeast rice is used medicinally.

#### **Red yeast rice has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>High cholesterol</b> (page 223)
★☆☆	<b>High triglycerides</b> (page 235)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Since A.D. 800, red yeast rice has been employed by the Chinese as both a food and a medicinal agent. Its therapeutic benefits as both a promoter of blood circulation and a digestive stimulant were first noted in the traditional Chinese pharmacopoeia, *Ben Cao Gang Mu-Dan Shi Bu Yi*, during the Ming Dynasty (1368–1644).<sup>2</sup> Practitioners of Traditional Chinese Medicine use red yeast rice to treat abdominal pain due to stagnant blood and dysentery, as well as external and internal trauma.<sup>3</sup> In addition to its therapeutic applications, red yeast rice has been used for centuries as a flavor enhancer, a food preservative, and a base for a Taiwanese alcoholic rice-wine beverage.<sup>4,5</sup>

#### **Active constituents**

In addition to rice starch, protein, **fiber** (page 512), sterols, and fatty acids, red yeast rice contains numerous active constituents, including monacolin K, dihydromonacolin, and monacolin I to VI.

Researchers have determined that one of the ingredients in red yeast rice, called monacolin K, inhibits the production of **cholesterol** (page 223) by stopping the action of a key enzyme in the liver (e.g., HMG-CoA reductase) that is responsible for manufacturing cholesterol.<sup>6</sup> The drug lovastatin (Mevacor) acts in a similar

fashion to this red yeast rice ingredient. However, the amount per volume of monacolin K in red yeast rice is small (0.2% per 5 mg) when compared to the 20–40 mg of lovastatin available as a prescription drug.<sup>7</sup> This has prompted researchers to suggest that red yeast rice may have other ingredients, such as sterols, that might also contribute to lowering cholesterol.

Along with its evaluation in animal trials,<sup>8</sup> red yeast rice has been clinically investigated as a therapy for reducing **cholesterol** (page 223) in two human trials. In one trial, both men and women taking 1.2 grams (approximately 13.5 mg total monacolins) of a concentrated red yeast rice extract per day for two months had significant decreases in serum cholesterol levels.<sup>9</sup> In addition, people taking red yeast rice had a significant increase in HDL (“good”) cholesterol and a decrease in LDL (“bad”) cholesterol. Elevated **triglycerides** (page 235) were also found to be lowered.

A double-blind trial at the UCLA School of Medicine determined that red yeast rice in the amount of 2.4 grams per day (approximately 10 mg total monacolins) in capsules significantly decreased total- and LDL-cholesterol levels in a sample of people with elevated cholesterol after 12 weeks of therapy. Triglycerides were also reduced in those taking red yeast rice. However, unlike the original study, HDL values did not increase substantially.<sup>10</sup>

#### How much is usually taken?

The red yeast rice used in various studies was a proprietary product called Cholestin, which contains ten different monacolins. The amount of Cholestin used in these studies was 1.2–2.4 grams (5–10 mg of monacolins) per day in divided amounts for 8–12 weeks.<sup>11, 12</sup>

**Note:** Cholestin has been banned in the United States, as a result of a lawsuit alleging patent infringement.

Other red yeast rice products currently on the market differ from Cholestin in their chemical makeup. None contain the full complement of ten monacolin compounds that are present in Cholestin, and some contain a potentially toxic fermentation product called citrinin.<sup>13</sup> Until further information is available, red yeast rice products other than Cholestin cannot be recommended.

#### Are there any side effects or interactions?

The Cholestin brand of red yeast rice has been generally well tolerated with possible temporary mild side effects

such as **heartburn** (page 260), gas, and dizziness.<sup>14</sup> This product should not be used by people with liver disorders<sup>15</sup> and its safety during **pregnancy** (page 363) has not been established. As in the case of medications that inhibit HMG-CoA, it is advisable that people using red yeast rice products also supplement 30–60 mg of **coenzyme Q<sub>10</sub>** (page 496) daily.

There is one case report of muscle weakness and joint pain occurring in a man who was taking red yeast rice.<sup>16</sup> Because the man was also taking several prescription drugs, it was not clear whether the symptoms were caused by red yeast rice. The report should be taken seriously, however, since muscle problems are common side effects of prescription HMG CoA-reductase inhibitors.

## REISHI

**Common names:** Ling chih, ling zhi

**Botanical name:** *Ganoderma lucidum*

#### Parts used and where grown

Reishi mushrooms grow wild on decaying logs and tree stumps in the coastal provinces of China. The fruiting body of the mushroom is employed medicinally. Reishi grows in six different colors, but the red variety is most commonly used and commercially cultivated in North America, China, Taiwan, Japan, and Korea.<sup>1</sup>

**Reishi has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Altitude sickness <b>Diabetes</b> (page 152) <b>Hepatitis</b> (page 220) <b>HIV support</b> (page 239) <b>Hypertension</b> (page 246) <b>Infection</b> (page 265)

#### Historical or traditional use (may or may not be supported by scientific studies)

Reishi has been used in Traditional Chinese Medicine for at least 2,000 years.<sup>2</sup> The Chinese name *ling zhi* translates as the “herb of spiritual potency” and was highly prized as an elixir of immortality.<sup>3</sup> Its Traditional

Chinese Medicine indications include treatment of general fatigue and weakness, **asthma** (page 32), **insomnia** (page 270), and **cough** (page 139).<sup>4</sup>

### Active constituents

Reishi contains several major constituents, including sterols, coumarin, mannitol, polysaccharides, and triterpenoids called ganoderic acids. Ganoderic acids may lower **blood pressure** (page 246) as well as decrease LDL ("bad") **cholesterol** (page 223). These specific triterpenoids also help reduce blood platelets from sticking together—an important factor in lowering the risk for **coronary artery disease** (page 38). While human research has been reported that demonstrates some efficacy for the herb in treating altitude sickness and chronic **hepatitis B** (page 220), these uses still need to be confirmed in well-designed human trials.<sup>5</sup> Animal studies and some very preliminary trials in humans suggest reishi may have some beneficial action in people with **diabetes mellitus** (page 152) and **cancer** (page 87).<sup>6</sup> Two controlled clinical trials have investigated the effects of reishi on **high blood pressure** (page 246) in humans and both found it could lower blood pressure significantly compared to a placebo or controls.<sup>7,8</sup> The people with hypertension in the second study had previously not responded to medications, though these were continued during the study.

### How much is usually taken?

Reishi can be taken either as 1.5–9 grams per day of the crude dried mushroom, 1–1.5 grams per day in powdered form, 1 ml per day of tincture, or as a tea.<sup>9</sup>

### Are there any side effects or interactions?

Side effects from reishi can include dizziness, dry mouth and throat, nosebleeds, and abdominal upset. These rare effects may develop with continuous use over three to six months.<sup>10</sup> **Pregnant** (page 363) or breast-feeding women should consult a physician before taking reishi.

## RHODIOLA

**Common name:** Golden root, roseroot

**Botanical name:** *Rhodiola rosea*

### Parts used and where grown

There are some 50 species of rhodiola, but it is the fragrant root of the species *Rhodiola rosea* that is used

medicinally. *Rhodiola rosea* grows throughout the mountainous regions in the higher latitudes and elevations of the Northern hemisphere.

**Rhodiola has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Athletic performance</b> (page 43) (to improve endurance) Fatigue Mental performance

### Historical or traditional use (may or may not be supported by scientific studies)

Rhodiola has long been used in traditional medicine, primarily in Russia and Scandinavia.<sup>1</sup> The Vikings used rhodiola to enhance physical strength and endurance, and it was commonly used by many Northern peoples to treat fatigue, poor physical endurance, nervous system disorders, and infections, and to enhance fertility. Rhodiola was included in the first Swedish Pharmacopeia, and Dioscorides, the Greek physician, reported on its use in his treatise *De Materia Medica*. In middle Asia, rhodiola was considered a premier treatment for colds and flu during the severe winters that occur there.

### Active constituents

Rhodiola contains a number of potentially active compounds, including phenylpropanoids (rosavin, rosin, rosarin); phenylethanol derivatives (salidroside [also known as rhodioloside], tyrosol]; flavonoids (rodiolin, rodionin, rodiosin, acetylrodalgin, tricin); monoterpenes (rosiridol, rosarinidin); triterpenes (daucosterol, beta-sitosterol); and phenolic acids (chlorogenic, hydroxycinnamic, and gallic acids). The presence of rosavin distinguishes the species *R. rosea* from other rhodiolas, and many products are standardized to rosavin content to ensure that they contain the proper species.

There are numerous animal and test tube studies showing that rhodiola has both a stimulating and a sedating effect on the central nervous system (depending on intake amount); enhances physical endurance; improves thyroid, thymus, and adrenal function; protects the nervous system, heart, and liver; and has antioxidant and anticancer properties.<sup>2</sup>

### How much is usually taken?

Rhodiola has a more stimulating effect at lower amounts, and a more sedating effect at higher amounts. In medical treatment, the usual amounts taken are 200 to 600 mg per day of a standardized extract to at least 3% rosavins and 0.8 to 1% salidroside.<sup>3</sup> The nonstandardized amount would be 1 gram three times daily of the root, the amount for the alcoholic extract (40% alcohol) is 5 to 40 drops two to three times per day (with a weight to volume ratio of 1:1 to 1:5). Rhodiola is usually taken before meals.

### Are there any side effects or interactions?

The safety of rhodiola has not been firmly established. However, rhodiola has a history of centuries of folk use and has been the subject of many clinical studies. No side effects or interactions have been reported. Animal studies indicate that rhodiola has a low level of toxicity, and that there is a huge margin of safety at the typical recommended intake amounts.<sup>4</sup> There is no information available about the safety of rhodiola in pregnancy or lactation.

## ROOIBOS

**Common name:** Bushman tea, red bush tea

**Botanical name:** *Aspalathus linearis*

### Parts used and where grown

Rooibos is a nitrogen-fixing shrub native to South Africa. Its leaves are fermented and sun dried for use as a tea.

**Rooibos has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Allergies (page 14) Anti-aging Cancer prevention Indigestion (page 260)

### Historical or traditional use (may or may not be supported by scientific studies)

Rooibos is a pleasant-tasting beverage that has been used traditionally to soothe digestion and relieve stomach cramps, colic, and diarrhea. Rooibos tea has also

been used to relieve allergies and eczema, and to slow aging.

### Active constituents

Rooibos is completely caffeine free and, unlike black tea (*Camellia sinensis*), does not contain tannins that may interfere with iron absorption. Rooibos is rich in flavonoids, polyphenols, and phenolic acids (including aspalathin, (+)-catechin, isoquercitrin, luteolin, quercetin, rutin, caffeic acid, ferulic acid, and vanillic acid). The polyphenol aspalathin is unique to rooibos. The plant also contains oligosaccharides, polysaccharides, and a variety of minerals, though at levels that are of questionable clinical relevance.<sup>1</sup>

Preliminary studies show that rooibos has antimutagenic and antioxidant properties.<sup>2, 3, 4, 5</sup> It has also shown some ability to prevent radiation damage in animals.<sup>6, 7, 8</sup> This research somewhat supports rooibos's traditional use to slow the aging process, and its modern use as a cancer preventative. Laboratory and animal studies indicate that it affects antibody production and has anti-HIV activity.<sup>9, 10, 11</sup> These studies raise the possibility that the herb could be useful in aiding deficient immune responses in allergies, AIDS, and infections. No clinical trials have yet been published on this herb, however, so its efficacy is still unknown.

### How much is usually taken?

A tea can be made by steeping 1 to 4 teaspoons (5 to 20 grams) of rooibos in 1 cup (240 ml) of water for up to ten minutes. Three cups of this tea per day may be drunk, with or without food.<sup>12</sup>

### Are there any side effects or interactions?

As rooibos has not been studied scientifically in humans, there is no information available about its safety in pregnancy or lactation or in people with kidney or liver failure. However, it is generally considered a very safe herb, and there are no known side effects, contraindications, or drug interactions.<sup>13</sup>

## ROSEMARY

**Botanical name:** *Rosmarinus officinalis*

### Parts used and where grown

Rosemary is a small, fragrant evergreen shrub. The rosemary plant originated in the countries surrounding the

Mediterranean Sea. However, it now grows in North America as well. The leaf is used in herbal medicine.

**Rosemary has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Atherosclerosis</b> (page 38) <b>Chronic candidiasis</b> (page 109) <b>Indigestion</b> (page 260) <b>Infection</b> (page 265) <b>Rheumatoid arthritis</b> (page 387) (topical)

**Historical or traditional use (may or may not be supported by scientific studies)**

Throughout history, rosemary was used to preserve meats.<sup>1</sup> It has long played a role in European herbalism and popular folklore. Sprigs of rosemary were considered a love charm, a sign of remembrance, and a way to ward off the plague. Rosemary was used by herbalists as a tonic for the elderly and to help with **indigestion** (page 260).<sup>2</sup> In ancient China, rosemary was used for headaches and topically for baldness.<sup>3</sup>

**Active constituents**

A number of constituents have shown activity in the test tube. The volatile oil, including eucalyptol (cineole), is considered to have potent antibacterial effects<sup>4</sup> and to relax smooth muscles in the lungs.<sup>5</sup> Rosmarinic acid has **antioxidant** (page 467) activity<sup>6</sup> and another ingredient of rosemary, known as carnosol, inhibits **cancer** (page 87) formation in animal studies.<sup>7</sup> No human studies have confirmed rosemary's use for these conditions.

**How much is usually taken?**

The German Commission E monograph suggests  $\frac{3}{4}$  to  $1\frac{1}{2}$  tsp (4 to 6 grams) of rosemary leaf per day.<sup>8</sup> A tea can be prepared by adding 2 teaspoons (10 grams) of herb to 1 cup (250 ml) boiling water and allowing it to steep in a covered container for 10 to 15 minutes. This tea can be taken several times per day. Rosemary tincture,  $\frac{1}{2}$  to 1 teaspoon (2 to 5 ml) three times per day, may also be used. The concentrated volatile oil should not be taken internally.

**Are there any side effects or interactions?**

There is no evidence to indicate that intermittent intake of moderate amounts of rosemary poses any threat

during breast-feeding. However, internal intake of the herb and oil should be avoided during **pregnancy** (page 363) because the oil may act as an abortifacient (an agent that may induce an abortion).<sup>9</sup>

An extract of rosemary taken with a meal by healthy women inhibited the absorption of non-heme iron (e.g., the form of iron in plant foods) by 15%.<sup>10</sup> Frequent use of rosemary could, in theory, promote the development of iron deficiency in susceptible individuals.

## SAGE

**Botanical name:** *Salvia officinalis*

**Parts used and where grown**

Sage is a silvery-green shrub with very fragrant leaves. The most commonly cultivated species of sage originally came from the area around the Mediterranean but now also grows in North America. The leaves of this common kitchen herb are used in medicine as well as in cooking.<sup>1</sup>

**Sage has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Alzheimer's disease</b> (page 19) Excessive perspiration <b>Gingivitis</b> (page 203) (periodontal disease) (as mouthwash, in combination with <b>peppermint</b> [page 726] oil, menthol, <b>chamomile</b> [page 656] tincture, expressed juice from <b>echinacea</b> [page 669], <b>myrrh</b> [page 713] tincture, clove oil, and <b>caraway</b> [page 651] oil) <b>Indigestion</b> (page 260) <b>Menopause</b> (page 311) (in combination with <b>alfalfa</b> [page 623])
★★★	<b>Infection</b> (page 265) <b>Menopause</b> (page 311) <b>Pregnancy and postpartum support</b> (page 363) <b>Sore throat</b> (page 129)

**Historical or traditional use (may or may not be supported by scientific studies)**

Sage has one of the longest histories of use of any culinary or medicinal herb. It was used by herbalists externally to treat sprains, swelling, ulcers, and bleeding.<sup>2</sup>

Internally, a tea made from sage leaves has had a long history of use to treat **sore throats** (page 129) and **coughs** (page 139)—often used as a gargle. It was also used by herbalists for rheumatism, excessive menstrual bleeding, and to dry up a mother's milk when nursing was stopped. It was particularly noted for strengthening the nervous system, improving memory, and sharpening the senses.<sup>3</sup> Sage was officially listed in the *United States Pharmacopoeia* from 1840 to 1900.

#### Active constituents

The volatile oil of sage contains the constituents alpha- and beta-thujone, camphor, and cineole.<sup>4</sup> It also contains rosmarinic acid, tannins, and flavonoids. In modern European herbal medicine, a gargle of sage tea is commonly recommended to treat **sore throat** (page 129), inflammations in the mouth, and **gingivitis** (page 203) (inflammation of the gums).<sup>5</sup> Test tube studies have found that sage oil has antibacterial, antifungal, and antiviral activity which may partially explain the effectiveness of sage for these indications.<sup>6</sup>

Sage is also approved in Germany for mild gastrointestinal upset and excessive sweating.<sup>7</sup> An unpublished, preliminary German study with people suffering from excessive perspiration found that either a dry leaf extract or an infusion of the leaf reduced sweating by as much as 50%.<sup>8</sup> A report from the United Kingdom indicates that herbalists there employ sage to treat symptoms of **menopause** (page 311) such as hot flashes.<sup>9</sup>

#### How much is usually taken?

For treatment of **sore throats** (page 129), inflammation in the mouth, or **gingivitis** (page 203), 3 grams of the chopped leaf can be added to 150 ml of boiling water and strained after 10 minutes.<sup>10</sup> This is then used as a mouthwash or gargle several times daily. Alternatively, one may use 5 ml of fluid extract (1:1) diluted in one glass of water, several times daily. For internal use, the same tea preparation described above may be taken three times per day.

#### Are there any side effects or interactions?

Concern has been expressed about the internal use of sage due to the presence of thujone.<sup>11</sup> Even when consumed in small amounts for long periods of time, thujone may cause increased heart rate and mental confusion. Very high amounts (several times greater than one receives if taking sage as instructed above), may lead to convulsions. If one takes sage internally, it is best to limit use to the amounts listed above and to

periods of no more than one to two weeks. Extracts of sage made with alcohol are likely to be higher in thujone than those made with water. Sage oil should never be consumed without being first diluted in water. Sage should not be used internally during **pregnancy** (page 363). These concerns do not extend to the use of sage as a gargle or mouth rinse. Sage should be avoided when fever is present.

## SANDALWOOD

**Botanical name:** *Santalum album*

#### Parts used and where grown

Sandalwood trees grow in India and other parts of Asia. The wood is renowned for carving and also yields the volatile oil used in herbal medicine.

**Sandalwood has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Infection (page 265)

#### Historical or traditional use (may or may not be supported by scientific studies)

Sandalwood oil was used traditionally by herbalists to treat skin diseases, **acne** (page 4), dysentery, gonorrhea, and a number of other conditions.<sup>1</sup> In Traditional Chinese Medicine, sandalwood oil is considered an excellent sedating agent.

#### Active constituents

The volatile oil contains high amounts of alpha- and beta-santalol. According to a test tube study, these small molecules possess antibacterial properties.<sup>2</sup> This makes it a potential topical treatment for skin infections. Synthetic sandalwood oil does not contain these active ingredients. Internal use of sandalwood is approved by the German Commission E for the supportive treatment of infections of the lower urinary tract (usually the urinary bladder).<sup>3</sup> However, clinical trials are lacking to support this use.

#### How much is usually taken?

The German Commission E monograph suggests  $\frac{1}{2}$  teaspoon (1–1.5 grams) of the volatile oil for the support-

ive treatment of **urinary tract infections** (page 436).<sup>4</sup> This should only be done under the supervision of a doctor. Treatment should not exceed six weeks. For external use, a few drops of sandalwood oil are dissolved in 6 ounces (180 ml) of water and applied directly to the infected area of skin several times daily.

#### **Are there any side effects or interactions?**

Some people may experience mild skin irritation from topical application of sandalwood oil.<sup>5</sup> People with kidney disease should not use sandalwood internally. Until more is known, sandalwood oil should be avoided for internal use during **pregnancy** (page 363) and breast-feeding. Infants and children should not take sandalwood oil internally.

## SARSAPARILLA

**Botanical name:** *Smilax* spp.

#### **Parts used and where grown**

Many different species are called by the general name sarsaparilla. Various species are found in Mexico, South America, and the Caribbean. The root is used in herbal medicine.

**Sarsaparilla has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Eczema (page 177)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

In Mexico, sarsaparilla was used by herbalists for rheumatism, **cancer** (page 87), skin diseases, and a host of other conditions.<sup>1</sup> At the turn of the 20th century, there were reports of its use by herbalists for the treatment of leprosy.<sup>2</sup> Sarsaparilla also has a tradition of use in various women's health concerns and was rumored to have a **progesterone** (page 577)-like effect. Sarsaparilla was formerly a major flavoring agent in root beer.

#### **Active constituents**

Sarsaparilla contains steroid saponins, such as sarsasapogenin, which may mimic the action of some human

hormones. This property remains undocumented, however. Sarsaparilla also contains phytosterols, such as **beta-sitosterol** (page 471), which may contribute to the anti-inflammatory effect of this herb. Reports have shown anti-inflammatory<sup>3</sup> and liver-protecting<sup>4</sup> effects for this herb. Similar reports on the effect of sarsaparilla on psoriasis occur in early European literature.<sup>5</sup>

#### **How much is usually taken?**

Sarsaparilla is often taken in capsules, 2–4 grams three times per day.<sup>6</sup> A tincture, 2–4 ml three times per day, may also be used.

#### **Are there any side effects or interactions?**

According to the German Commission E monograph, sarsaparilla may cause stomach irritation and temporary kidney irritation.<sup>7</sup> Sarsaparilla should not be taken during **pregnancy** (page 363) or breast feeding.

## SASSAFRAS

**Botanical name:** *Sassafras albidum*

#### **Parts used and where grown**

Sassafras is native to eastern North America. It is a tree that can grow up to 90 feet tall, and it has distinctive three-fingered mitten-shaped leaves, as well as other leaf shapes. The inner bark of the root is used medicinally and in the preparation of beverages.

**Sassafras has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	Fever Lice (topical oil) Rheumatism <b>Urinary tract infection</b> (page 436) (as irrigation therapy)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Sassafras was used by Native Americans for many purposes, primarily for infections and gastrointestinal problems.<sup>1</sup> Sassafras was one of the first and largest exports from the New World back to Europe as a beverage

and medicine.<sup>2</sup> Commercially, the pleasant tasting volatile oil was valued as a flavoring agent in root beer and similar beverages. Eclectic physicians in the late 19th and early 20th centuries considered sassafras a useful diaphoretic (a substance that causes sweating) and diuretic plant, primarily for relieving rheumatism and fevers, and as part of the treatment of **urinary tract infections** (page 436).<sup>3</sup>

### Active constituents

The volatile oil of sassafras is believed to be the major active constituent of the plant. This oil contains up to 85% of the terpenoid known as safrole.<sup>4</sup> Safrole causes liver cancer when given to laboratory animals in high doses for long periods of time.<sup>5</sup> Sassafras bark, sassafras oil, and safrole are currently prohibited by the U.S. Food and Drug Administration from use as flavorings or food additives. Human studies are lacking to verify the efficacy of sassafras for any condition. However, one case study has been published showing that sassafras acted as a diaphoretic in an otherwise healthy woman.<sup>6</sup> While the amount of sassafras that could potentially cause cancer in humans remains unknown, one cup of strong sassafras tea is reported to contain as much as 200 mg of safrole, an amount that is four times higher than the amount considered potentially hazardous to humans if consumed regularly.<sup>7</sup>

### How much is usually taken?

The safety of long-term internal use of sassafras has not been proven. Only guaranteed safrole-free products should be consumed. Note that safrole-containing food products are illegal in the United States and Canada.<sup>8</sup> Some sources suggest a dilute tincture can be used in the amount of 1 to 2 ml three times per day.<sup>9</sup> Volatile oil of sassafras can be applied topically three times per day for lice, but should never be taken internally.<sup>10</sup>

### Are there any side effects or interactions?

Safrole causes liver cancer if given to laboratory animals “in high doses and for extended periods of time.”<sup>11</sup> This requires metabolism of safrole by the liver into other toxic compounds, though the liver also removes some of these compounds for excretion through the urine.<sup>12, 13</sup> The overall risk of sassafras causing cancer in humans is thought to be low because it is only weakly active and the amounts normally consumed are low.<sup>14</sup> To eliminate the risk, sassafras products that contain safrole should not be consumed.

Safrole and its toxic metabolites do cross the placenta

and enter breast milk in laboratory animals, and thus sassafras should be avoided by women who are pregnant or breast-feeding.<sup>15</sup>

## SAW PALMETTO

**Common name:** Sabal

**Botanical names:** *Serenoa serrulata*, *Serenoa repens*, *Sabal serrulata*

### Parts used and where grown

Saw palmetto (sometimes referred to as sabal in Europe) is a native of the southeast United States. The berries of the plant are used medicinally.

**Saw palmetto has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Benign prostatic hyperplasia (BPH)</b> (page 58)
★☆☆	<b>Prostatitis</b> (page 377) (NBP)

### Historical or traditional use (may or may not be supported by scientific studies)

In the early part of the twentieth century, saw palmetto berry tea was commonly recommended by herbalists for a variety of urinary tract ailments in men. Some believed the berry increased sperm production and sex drive in men.

### Active constituents

The liposterolic (fat-soluble) extract of saw palmetto provides concentrated amounts of free fatty acids and sterols. One study with a saw palmetto extract suggests that it reduces the amount of dihydrotestosterone (DHT) (an active form of testosterone) binding in the part of the prostate surrounding the urethra (the tube carrying urine from the bladder).<sup>1</sup> Test tube studies also suggest that saw palmetto weakly inhibits the action of 5-alpha-reductase, the enzyme responsible for converting testosterone to DHT.<sup>2</sup> In test tubes, saw palmetto also inhibits the actions of growth factors and inflammatory substances that may contribute to **benign prostatic hyperplasia** (page 58) (BPH). Contrary to some

opinions, saw palmetto does not have an estrogen-like effect in men's bodies.

Over the last decade, double-blind clinical trials have proven that 320 mg per day of the liposterolic extract of saw palmetto berries is a safe and effective treatment for the symptoms of **BPH** (page 58). A recent review of studies, published in the *Journal of the American Medical Association*, concluded that saw palmetto extract was as effective as finasteride (Proscar) in the treatment of BPH.<sup>3</sup> The clinical effectiveness of saw palmetto has been shown in trials lasting six months to three years.

A three-year trial in Germany found that taking 160 mg of saw palmetto extract twice daily reduced nighttime urination in 73% of patients and improved urinary flow rates significantly.<sup>4</sup> In a double-blind trial, 160 mg of saw palmetto extract taken twice daily was found to treat BPH as effectively as finasteride (Proscar) without side effects, such as loss of libido.<sup>5</sup>

Saw palmetto extract has also been combined with a **nettle** (page 714) root extract to successfully treat BPH. One trial using a combination of saw palmetto extract (320 mg per day) and nettle root extract (240 mg per day) showed positive actions on symptoms of BPH (e.g. improved urine flow, decreased nighttime urination, etc.) over a one-year treatment period.<sup>6</sup> Another study compared the same combination to finasteride for one year with positive results.<sup>7</sup>

#### How much is usually taken?

For early-stage **BPH** (page 58), 160 mg per day of liposterolic saw palmetto herbal extract in capsules is taken two times per day. One trial suggested that 320 mg once per day may be equally effective.<sup>8</sup> It may take four to six weeks to see results with BPH. If improvement is noted, the saw palmetto should be used continuously. It is important to work closely with a urologist to determine clinical improvement. Although it has not been tested for efficacy, saw palmetto is occasionally taken as a tea made with 5–6 grams of the powdered dried fruit. Ground, nonstandardized berry preparations (1–2 grams per day) and liquid extracts of whole herb at 5–6 ml per day are also sometimes used but have not been specifically tested.

#### Are there any side effects or interactions?

No significant side effects have been noted in clinical trials with saw palmetto extracts. However, in rare cases, saw palmetto can cause stomach problems,<sup>9</sup> and one individual who was taking saw palmetto developed severe bleeding during surgery.<sup>10</sup> According to some clinical

trials, saw palmetto extract does not appear to interfere with accurate measuring of prostate-specific antigen (PSA)—a marker for **prostate cancer** (page 371).<sup>11</sup> One test tube study found that saw palmetto did not prevent the release of PSA from prostate cells.<sup>12</sup> Saw palmetto is most effective in managing symptoms of BPH but has not been shown to aggressively shrink the size of the prostate. BPH can only be diagnosed by a physician (preferably a urologist). Use of saw palmetto extract for BPH should only occur after a thorough workup and diagnosis by a doctor. There are no proven uses of saw palmetto for women.

## SCHISANDRA

**Common name:** Wu-wei-zi

**Botanical name:** *Schisandra chinensis*

#### Parts used and where grown

Schisandra is a woody vine with numerous clusters of tiny, bright red berries. It is distributed throughout northern and northeast China and the adjacent regions of Russia and Korea.<sup>1</sup> The fully ripe, sun-dried fruit is used medicinally. It is purported to have sour, sweet, salty, hot, and bitter tastes. This unusual combination of flavors is reflected in schisandra's Chinese name wu-wei-zi, meaning "five taste fruit."

**Schisandra has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Irritable bowel syndrome</b> (page 280) (Chinese herbal combination formula containing <b>wormwood</b> [page 762], <b>ginger</b> [page 680], <b>bupleurum</b> [page 647], schisandra, dan shen, and other extracts)
★☆☆	<b>Common cold/sore throat</b> (page 129) <b>Fatigue</b> <b>Hay fever</b> (page 211) (Sho-seiryu-to: contains <b>licorice</b> [page 702], cassia bark, schisandra, ma huang [ephedra], <b>ginger</b> [page 680], peony root, pinellia, and asiasarum root) <b>Hepatitis</b> (page 220) <b>Infection</b> (page 265) <b>Liver support</b> <b>Stress</b>

### **Historical or traditional use (may or may not be supported by scientific studies)**

A classical treatise on Chinese herbal medicine, *Shen Nung Pen Tsao Ching*, describes schisandra as a high-grade herbal drug useful for a wide variety of medical conditions—especially as a kidney tonic and lung astringent. In addition, other textbooks on Traditional Chinese Medicine note that schisandra is useful for **coughs** (page 139), night sweats, **insomnia** (page 270), thirst, and physical exhaustion.<sup>2</sup> Adaptogenic herbs, like schisandra, have been used in Traditional Chinese Medicine to improve the ability of the body to respond to stress.

### **Active constituents**

The major constituents in schisandra are lignans (schizandrin, deoxyschizandrin, gomisin, and pregnomisin) found in the seeds of the fruit. Modern Chinese research suggests these lignans have a protective effect on the liver and an immunomodulating effect. Two human trials completed in China (one double-blind and the other preliminary) have shown that schisandra may help people with chronic viral **hepatitis** (page 220).<sup>3, 4</sup> Schisandra lignans appear to protect the liver by activating the enzymes in liver cells that produce **glutathione** (page 531), an important **antioxidant** (page 467) substance.<sup>5</sup>

Schisandra fruit may also have an adaptogenic action, much like the herb **Asian ginseng** (page 630), but with weaker effects. Laboratory work suggests that schisandra may improve work performance, build strength, and help to reduce fatigue.<sup>6</sup>

### **How much is usually taken?**

Use of schisandra fruit ranges from 1.5–15 grams per day.<sup>7</sup> The tincture, 2–4 ml three times per day, can also be used.

### **Are there any side effects or interactions?**

Side effects involving schisandra are uncommon but may include abdominal upset, decreased appetite, and skin rash.<sup>8</sup>

## **SENNA**

**Botanical names:** *Cassia senna*, *Cassia angustifolia*

### **Parts used and where grown**

The senna shrub grows in India, Pakistan, and China. The leaves and pods are used medicinally.

**Senna has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Constipation</b> (page 137)
★★☆	Bowel Surgery (preparation for)

### **Historical or traditional use (may or may not be supported by scientific studies)**

People in northern Africa and southwestern Asia have used senna as a laxative for centuries. It was considered a “cleansing” herb because of its cathartic effect. In addition, the leaves were sometimes made into a paste and applied to various skin diseases. Ringworm and **acne** (page 4) were both treated in this way.

### **Active constituents**

Senna contains hydroxyanthracene glycosides known as sennosides. These glycosides stimulate colon activity and thus have a laxative effect. Also, these glycosides increase fluid secretion by the colon, with the effect of softening the stool and increasing its bulk.<sup>1</sup> Double-blind trials have confirmed the benefit of senna in treating **constipation** (page 137).<sup>2, 3</sup> Constipation induced by drugs such as the anti-**diarrhea** (page 163) medicine loperamide (Imodium) has also been shown to be improved by senna in a clinical trial.<sup>4</sup>

A double-blind trial showed that senna was more effective as a preparatory agent for bowel surgery than the commonly used polyethylene glycol (PEG).<sup>5</sup> Patients scheduled to undergo bowel surgery received either 120 mg of senna in a glass of water or 118 mg of PEG in about 2–3 quarts of water the night before surgery. Surgeons rated the efficacy of senna at clearing the bowels at 70%, compared to 58% efficacy for PEG. Supplementation with senna for this purpose should always be supervised by the surgeon.

### **How much is usually taken?**

People using over-the-counter senna products should carefully follow label instructions. An extract in capsules or tablets providing 20–60 mg of sennosides per day is sometimes recommended.<sup>6</sup> This can be continued for a maximum of ten days. Use beyond ten days is strongly discouraged. If constipation is not alleviated within ten days, people should seek the help of a healthcare professional.

### Are there any side effects or interactions?

Some people may develop a dependency on senna for normal bowel movements. Therefore, senna must not be used for more than ten consecutive days. Chronic senna use can also cause loss of fluids, low **potassium** (page 572) levels and **diarrhea** (page 163), all of which can lead to dehydration and potentially negative effects on the heart and muscles. The safety of senna during **pregnancy** (page 363) and breast-feeding is controversial. Most guidelines suggest avoiding senna during the first trimester of pregnancy.<sup>7, 8</sup> It is best to consult a physician. Senna is not recommended for children under the age of ten years. People with **Crohn's disease** (page 141), **ulcerative colitis** (page 433), appendicitis, intestinal obstructions, and abdominal pain should not supplement with senna.<sup>9</sup>

## SHIITAKE

**Common name:** Hua gu

**Botanical name:** *Lentinus edodes*

### Parts used and where grown

Wild shiitake mushrooms are native to Japan, China, and other Asian countries and typically grow on fallen broadleaf trees. Shiitake is now widely cultivated throughout the world, including the United States. The fruiting body is used medicinally.

**Shiitake has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Hepatitis</b> (page 220) <b>HIV support</b> (page 239) <b>Infection</b> (page 265) <b>Prostate cancer</b> (page 371)

### Historical or traditional use (may or may not be supported by scientific studies)

(may or may not be supported by scientific studies): Shiitake has been revered in Japan and China as both a food and medicinal herb for thousands of years. Wu Ri, a physician from the Chinese Ming Dynasty era (A.D. 1368–1644), wrote extensively about this mushroom,

noting its ability to increase energy, cure **colds** (page 129), and eliminate worms.<sup>1</sup>

### Active constituents

Shiitake contains proteins, fats, carbohydrates, soluble **fiber** (page 512), vitamins, and minerals. In addition, shiitake's key ingredient—found in the fruiting body—is a polysaccharide called lentinan. Commercial preparations employ the powdered mycelium of the mushroom before the cap and stem grow. This preparation is called *lentinus edodes* mycelium extract (LEM). LEM is rich in polysaccharides and lignans.

One preliminary trial suggested that oral shiitake may be useful for people with **hepatitis B** (page 220).<sup>2</sup> A highly purified, intravenous form of lentinan is used in Japan and has been reported to increase survival in people with recurrent stomach **cancer** (page 87), particularly when used in combination with chemotherapy.<sup>3</sup> Similar findings have been found in one small clinical trial with people suffering from pancreatic cancer.<sup>4</sup> Case reports from Japan suggest that intravenous lentinan may be helpful in treating people with **HIV** (page 239) infection.<sup>5</sup> However, large-scale clinical trials to confirm this action have not yet been performed.

Oral supplementation of lentinan from shiitake has been shown to significantly reduce the recurrence rate of genital warts (*condyloma acuminata*). A preliminary trial involving a group of men and women with genital warts found that those who took 12.5 mg of lentinan twice a day for two months after laser surgery had significantly fewer recurrences (10.53% recurrence rate) compared to those who only had the laser surgery (47.06% recurrence rate).<sup>6</sup>

### How much is usually taken?

The traditional intake of the whole, dried shiitake mushroom is 6–16 grams per day.<sup>7</sup> The mushroom is typically eaten in soups or taken as a decoction (i.e., boiled for 10–20 minutes, cooled, strained, and drunk). Recommended intake of LEM is 1–3 grams two to three times per day. Purified lentinan is considered a drug in Japan and is not currently available as an herbal supplement in North America.

### Are there any side effects or interactions?

Shiitake has an excellent record of safety but has been known to induce temporary **diarrhea** (page 163) and abdominal bloating when used in high amounts (above 15–20 grams per day). Its safety during **pregnancy** (page 363) and breast feeding has not yet been established.

## SLIPPERY ELM

**Botanical names:** *Ulmus rubra*, *Ulmus fulva*

### Parts used and where grown

The slippery elm tree is native to North America, where it still grows primarily. The inner bark of the tree is the main part used for medicinal preparations.

**Slippery elm has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Common cold/sore throat</b> (page 129) <b>Cough</b> (page 139) <b>Crohn's disease</b> (page 141) <b>Gastritis</b> (page 195) <b>Gastroesophageal reflux disease</b> (page 198) (GERD) <b>Heartburn</b> (page 260) (symptom relief)

### Historical or traditional use (may or may not be supported by scientific studies)

Native Americans found innumerable medicinal and other uses for this tree. Canoes, baskets, and other household goods were made from the tree and its bark. Slippery elm was also used internally for conditions such as **sore throats** (page 129) and **diarrhea** (page 163).<sup>1</sup> As a poultice, it was considered a remedy for many inflammatory skin conditions.

### Active constituents

The mucilage of slippery elm, found in the inner bark, gives it the soothing effect for which it is known.<sup>2</sup> In people with **heartburn** (page 260), the mucilage appears to act as a barrier against the damaging effects of acid on the esophagus. It may also have an anti-inflammatory effect locally in the stomach and intestines. This soothing effect may also extend to the throat. Clinical research, verifying these effects in humans has not been conducted.

### How much is usually taken?

The dried inner bark in capsules or tablets, 800–1,000 mg three to four time per day, may be used. A tea can also be made by boiling ½–2 grams of the bark in 200 ml of water for ten to fifteen minutes, then cooled before drinking. Three to four cups a day can be used.<sup>3</sup>

Tincture, 5 ml three times per day, can be taken as well. Slippery elm is also an ingredient of some sore throat and cough lozenges.

### Are there any side effects or interactions?

Slippery elm is quite safe. There are no known reasons to avoid its use during **pregnancy** (page 363) or breast feeding. However, because it is so mucilaginous, it may interfere with the absorption of medicine taken at the same time.

## ST. JOHN'S WORT

**Common name:** Klamath weed

**Botanical name:** *Hypericum perforatum*

### Parts used and where grown

St. John's wort is found in Europe and the United States. It is especially abundant in northern California and southern Oregon. The above-ground (aerial) parts of the plant are gathered during the flowering season.

**St. John's wort has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Depression</b> (page 145) <b>Eczema (topical application)</b> (page 177) <b>Seasonal affective disorder</b> (page 397) Somatoform disorders
★☆☆	<b>Anxiety</b> (page 30) <b>Cold sores</b> (page 90) <b>Ear infections (recurrent)</b> (page 383) <b>HIV support</b> (page 239) <b>Infection</b> (page 265) <b>Menopause</b> (page 311) <b>Ulcerative colitis</b> (page 433) <b>Wound healing</b> (page 319)

### Historical or traditional use (may or may not be supported by scientific studies)

In ancient Greece, St. John's wort was used to treat many ailments, including sciatica and poisonous reptile bites. In Europe, St. John's wort was used by herbalists for the topical treatment of **wounds** (page 319) and **burns** (page 85). It is also a folk remedy for kidney and lung ailments as well as for **depression** (page 145).

### Active constituents

The major constituents in St. John's wort include hypericin and other dianthrone, **flavonoids** (page 516), xanthones, and hyperforin.<sup>1</sup> While it was previously thought the antidepressant actions of St. John's wort were due to hypericin and the inhibition of the enzyme monoamine oxidase,<sup>2</sup> current research has challenged this belief, focusing on other constituents, such as hyperforin, and flavonoids.<sup>3, 4, 5</sup> Test tube studies suggest that St. John's wort extracts may exert their antidepressant actions by inhibiting the reuptake of the neurotransmitters serotonin, norepinephrine, and dopamine.<sup>6</sup> This action is possibly due to the constituent hyperforin.<sup>7</sup> St. John's wort is able to act as an antidepressant, by making more of these neurotransmitters available to the brain.

### How much is usually taken?

The standard recommendation for mild to moderate depression is 500–1,050 mg of St. John's wort extract per day.<sup>8, 9, 10</sup> Results may be noted as early as two weeks. Length of use should be discussed with a healthcare professional. For more severe depression, higher intakes may be used, under the supervision of a healthcare professional.

### Are there any side effects or interactions?

St. John's wort has a low incidence of side effects compared to prescription antidepressants. An adverse events profile of St. John's wort found that, of 14 controlled clinical trials, seven reported no adverse reactions, two had no information, and five reported a total of seven mild reactions.<sup>11</sup> Adverse effects reported included stomach upset, fatigue, itching, sleep disturbance, and skin rash. The rate of adverse reactions was always similar to that of the placebo. Additionally, in seven trials comparing St. John's wort with other antidepressants, the adverse reaction rate for St. John's wort was consistently lower than that of the antidepressant drugs with which it was compared.

St. John's wort can make the skin more sensitive to sunlight.<sup>12</sup> Therefore, fair-skinned people should be alert for any rashes or burns following exposure to the sun. Three cases of severe blistering and burns were reported in people taking St. John's wort internally or applying it topically and then being exposed to sunlight.<sup>13</sup> There is a case report of a woman experiencing neuropathy (nerve injury and pain) in sun-exposed skin areas after taking 500 mg of whole St. John's wort for four weeks.<sup>14</sup> Although St. John's wort has photosensi-

tizing properties, the severity of this reaction is not typical for people taking the herb.

People with a history of manic-depressive illness (**bipolar disorder** [page 61]) or a less severe condition known as hypomania, should avoid use of St. John's wort as it may trigger a manic episode.<sup>15, 16, 17, 18</sup>

There is a single case report in which ingestion of St. John's wort appeared to cause **high blood pressure** (page 246) in a 56-year-old man. The blood pressure returned to normal when the herb was discontinued.<sup>19</sup>

**Caution:** It is likely that there are many drug interactions with St. John's wort that have not yet been identified. St. John's wort stimulates a drug-metabolizing enzyme (cytochrome P450 3A4) that metabolizes at least 50% of the drugs on the market.<sup>20</sup> Consequently, St. John's wort could potentially interfere with a large number of medications. Individuals taking any medication should, therefore, consult with a physician before taking St. John's wort.

## STEVIA

**Common name:** Sweetleaf

**Botanical name:** *Stevia rebaudiana*

### Parts used and where grown

The stevia plant originally came from the rain forests of Brazil and Paraguay. It is now grown in those areas, as well as in Japan, Korea, Thailand, and China. It is most widely used as a non-sugar sweetener in food and drink, particularly because it does not appear to have any calories or affect on blood sugar like most natural sweeteners (like sugar or honey). The leaf is used in herbal preparations.

### Historical or traditional use (may or may not be supported by scientific studies)

The native peoples in South America used stevia primarily as a sweetener, a practice adopted by European colonists. The indigenous tribes also used stevia to treat **diabetes** (page 152).<sup>1</sup> During World War II, stevia was grown in England as a sugar substitute. The greatest use of stevia as a sweetener today can be found in Japan.

### Active constituents

Various glycosides, particularly stevioside, give stevia its sweetness. Stevioside is between 100 and 200 times

sweeter than sugar. Early reports suggested that stevia might reduce blood sugar (and therefore potentially help with **diabetes** [page 152]),<sup>2</sup> although this has not been confirmed in all reports.<sup>3</sup>

#### **How much is usually taken?**

Less than 1 gram per day can be used effectively as a sweetener. Usually, the powdered herb is added directly to tea or to food.

#### **Are there any side effects or interactions?**

Extensive reviews of human and animal data indicate stevia to be safe.<sup>4</sup> Stevia accounts for nearly 40% of the sweetener market in Japan and is commonly used in various parts of South America.<sup>5</sup>

## SUMA

**Common name:** Para todo

**Botanical names:** *Pfaffia paniculata, Hebanthe paniculata*

#### **Parts used and where grown**

Suma is a large shrubby vine native to the rain forests of the Amazon and other tropical regions of Latin America, including Brazil, Ecuador, Panama, Peru, and Venezuela.<sup>1</sup> The root of the plant is used medicinally.

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Although suma is claimed as an ancient Brazilian folk remedy, no confirmation of that statement is found in the modern literature on medicinal plants. Advocates have claimed suma is an immune enhancer, an adaptogen (helps combat stress), and that it possesses anti-cancer activities. Test tube studies do indicate possible anti-tumor activity of suma constituents called pfaffosides. Suma has been marketed as Brazilian ginseng, though it is not an adaptogen (a substance that invigorates or strengthens the system) and is not related to **Asian ginseng** (page 630) or **American ginseng** (page 625). In light of the lack of known traditional use, and of modern research confirming health benefits, use of suma is not recommended for any condition at this time.<sup>2</sup>

#### **Active constituents**

Suma root contains several major constituents, including the nortriterpene pfaffic acid, six pfaffic acid

saponins (pfaffosides A–F), pterosterone,ecdysterone, and ecdysteroid glycosides.<sup>3, 4</sup> Although widespread claims are made for this herb for the treatment of **chronic fatigue** (page 111), stress, **menopausal symptoms** (page 311), and **diabetes** (page 152), they are not supported by current human clinical research. What little research has been done focuses on the plant's anti-tumor, anti-inflammatory, and aphrodisiac effects and has been completed only in test tubes or with animals.<sup>5, 6, 7, 8</sup>

#### **How much is usually taken?**

Suma root, 500 to 1,000 mg two to three times per day, can be used.<sup>9</sup>

#### **Are there any side effects or interactions?**

Very little is known about the adverse effects of this herb. Saponins, such as the pfaffosides found in this plant, can cause nausea when taken in excessive quantities. Occupational inhalation of suma dust has been known to trigger **asthma** (page 32).<sup>10</sup> The safety of this plant has not been established for use during **pregnancy** (page 363) or breast-feeding.

## SUNDEW

**Botanical names:** *Drosera rotundifolia, Drosera ramentacea, Drosera intermedia, Drosera anglica*

#### **Parts used and where grown**

These carnivorous plants have their primary origins in East Africa and Madagascar but are cultivated throughout the world. The main species originally used in cough preparations in Germany, *D. rotundifolia*, *D. intermedia*, and *D. anglica*, are now rarely used currently due to threat of extinction. Instead, *D. ramentacea* and other *Drosera* species from Australia are employed. Herbal medicine preparations are made primarily from the roots, flowers, and fruit-like capsules.<sup>1</sup>

**Sundew has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Coughs</b> (page 139) (particularly dry and irritating)

### **Historical or traditional use (may or may not be supported by scientific studies)**

The historical use of sundew is similar to its use in modern herbal medicine. In 1685, Johann Schroder wrote in his book, *The Apothecary or a Treasure Chest of Valuable Medicines*, that sundew was a beneficial herb that “cures lung ailments and cures coughs.” Sundew tea was specifically recommended in Europe by herbalists for dry **coughs** (page 139), **bronchitis** (page 80), whooping cough, **asthma** (page 32), and “bronchial cramps.”<sup>2</sup>

### **Active constituents**

Naphthaquinones are believed to give sundew the antispasmodic (or relief from coughing spasms) effect that has made it such a popular **cough** (page 139) remedy in Europe.<sup>3</sup> These naphthaquinones include plumbagin, ramentone, ramentaceon, and biramentaceone. Pharmacological studies show a clear antispasmodic effect in the respiratory tract.<sup>4</sup> One naphthaquinone was found in an animal study to be comparable to codeine in its ability to suppress the impulse to cough. This finding has not been repeated in human studies, however. Based on this effect, sundew is often referred to as an herbal antitussive (a substance capable of preventing or relieving coughing). Human trials have shown its value either alone or in combination with other herbs for the treatment of coughs associated with **bronchitis** (page 80), pharyngitis, laryngitis, and even whooping cough.<sup>5</sup>

### **How much is usually taken?**

Adults and children older than 12 years of age may take  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoons (3 grams) per day.<sup>6</sup> To prepare tea, boiling water is poured over  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1 to 2 grams) of finely cut sundew root and above-ground parts, then strained after steeping for ten minutes. One cup (250 ml) may be taken three to four times daily. In Europe, liquid preparations of sundew are often combined with **thyme** (page 752), another antitussive, in cough syrups for adults and children. A tincture of sundew,  $\frac{1}{8}$ – $\frac{1}{4}$  teaspoon (0.5 to 1.0 ml) three times per day, is also sometimes used.

### **Are there any side effects or interactions?**

At the amounts listed above, sundew is thought to be safe.<sup>7</sup> Higher levels may lead to gastrointestinal irritation in some people. **Pregnant** (page 363) and breast-feeding women should avoid use of sundew.

## **SWEET ANNIE**

**Common names:** Qinghao, sweet wormwood

**Botanical name:** *Artemisia annua*

### **Parts used and where grown**

This inconspicuous herb originated in Europe and Asia and has since spread to North America. It is now a common weed around the world. The above ground parts of the plant are used medicinally.

**Sweet Annie has been used in connection with the following conditions** (refer to the individual health concern for complete information):

<b>Rating</b>	<b>Health Concerns</b>
★☆☆	Malaria (isolated artemisinin, an experimental drug)
★☆☆	Fever <b>Infectious diarrhea</b> (page 163) <b>Intestinal parasites</b> (page 343)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Ancient Chinese medical texts dating from around 150 B.C. suggest the use of sweet Annie for people with **hemorrhoids** (page 219).<sup>1</sup> Other writings from A.D. 340 are the first known to mention sweet Annie as a treatment for people with fevers.<sup>2</sup> It has been used ever since for a variety of infections in Traditional Chinese Medicine.

### **Active constituents**

Artemisinin, called qinghaosu in China where it was first discovered, is thought to account for the antimalarial activity of the plant.<sup>3, 4</sup> This compound is a sesquiterpene lactone and is believed to cause damage to the organisms that cause malaria inside the red blood cells they infect. Preliminary and double-blind trials, have shown that injections or oral use of artemisinin or similar compounds rapidly and effectively cure people with malaria.<sup>5</sup> A human trial has also found that artemisinin reduced mortality due to malaria by 50% compared with treatment with a standard quinoline anti-malarial drug.<sup>6</sup> Artemisinin-based drugs have not been studied for prevention of malaria. Test tube studies suggest artemisinin can kill other **parasites** (page 343) and bacteria,<sup>7</sup> possibly supporting the traditional

notion of using it for parasitic infections of the gastrointestinal tract.

### How much is usually taken?

Artemisinin-based drugs are not readily available in the United States or Europe and are still considered experimental. Sweet Annie cannot be substituted for artemisinin as a drug and cannot be used to treat people with malaria, a potentially lethal disease requiring immediate treatment. Traditionally, 3 grams of the powdered herb was taken each day.<sup>8</sup>

### Are there any side effects or interactions?

No serious adverse effects have been seen in clinical trials with artemisinin.<sup>9</sup> The use of the whole herb as well as artemisinin may cause upset stomach, loose stools, abdominal pain, and occasional fever.

## TEA TREE

**Common name:** Tea tree oil

**Botanical name:** *Melaleuca alternifolia*

### Parts used and where grown

The tea tree grows in Australia and Asia. This tall evergreen tree has a white, spongy bark. The oil from the leaves is used medicinally.

**Tea tree has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Acne</b> (page 4) (topical)
★★☆	<b>Athlete's foot</b> (page 42) (topical) Toenail fungal infection (topical)
★☆☆	<b>Chronic candidiasis</b> (page 109) (topical) <b>Halitosis</b> (page 209) (tea tree oil rinse or toothpaste) <b>HIV support</b> (page 239) <b>Infection</b> (page 265) (topical) <b>Vaginitis</b> (page 438) (topical) <b>Wound healing</b> (page 319) (oil, topical) <b>Yeast infection</b> (page 454) (topical)

### Historical or traditional use (may or may not be supported by scientific studies)

Australian Aborigines used the leaves to treat cuts and skin infections. They would crush the leaves and apply

them to the affected area. Captain James Cook and his crew named the tree "tea tree," using its leaves as a substitute for tea as well as to flavor beer. Australian soldiers participating in World War I were given tea tree oil as a disinfectant, leading to a high demand for its production.

### Active constituents

The oil contains numerous chemicals known as terpenoids. Australian standards were established for the amount of one particular compound, terpinen-4-ol, which must make up at least 30% and preferably 40–50% of the oil for it to be medically useful. Another compound, cineole, should make up less than 15% and preferably 2.5% of the oil. The oil kills fungus and bacteria, including those resistant to some antibiotics.<sup>1, 2</sup> For common **acne** (page 4), a double-blind trial compared the topical use of 5% tea tree oil to 5% benzoyl peroxide.<sup>3</sup> Although the tea tree oil was slower and less potent in its action, it had far fewer side effects and was thus considered more effective overall.

A double-blind trial found that a 10% tea tree oil cream was as effective as anti-fungal medicine at improving *symptoms* associated with **athlete's foot** (page 42), though it was not more effective than a placebo for eliminating the fungal infection.<sup>4</sup> A double-blind trial found 100% tea tree oil applied topically was as effective as the anti-fungal medicine clotrimazole (Lotrimin, Mycelex) for people with fungus affecting the toe nails, a condition known as onychomycosis.<sup>5</sup> In another double-blind trial with toenail fungus sufferers, a combination of 5% tea tree oil and 2% butenafine (Mentax), a synthetic anti-fungal drug, in a cream proved more effective than an unspecified concentration of tea tree oil in cream alone.<sup>6</sup> The results are not entirely surprising, as the tea tree product alone was probably not at a sufficiently high enough concentration to be effective.

A preliminary trial found that rinsing the mouth with 1 tablespoon (15 ml) tea tree oil solution four times daily effectively treated thrush (oral yeast infections) in **AIDS** (page 239) patients.<sup>7</sup> Solutions containing no more than 5% should be used orally and should never be swallowed.

A concern for hospital staff and patients is the spread of the bacteria *Staphylococcus aureus*—sometimes referred to as a "staph infection." One small clinical trial found that use of a 4% tea tree oil nasal ointment as well as a 5% tea tree oil body wash was slightly more ef-

fective than standard drugs used to prevent the spread of the bacteria.<sup>8</sup>

#### How much is usually taken?

Oil at a strength of 70–100% should be applied moderately at least twice per day to the affected areas of skin or nail.<sup>9</sup> For topical treatment of **acne** (page 4), the oil is used at a dilution of 5–15%. Concentrations as strong as 40% may be used—with extreme caution and qualified advice—as vaginal douches. For thrush in immune-compromised adults, tea tree oil diluted to 5% or less is used in the amount of 1 tablespoon (15 ml) four times daily (as a mouth rinse). Tea tree oil should never be swallowed.

#### Are there any side effects or interactions?

While tea tree oil can be applied to minor cuts and scrapes, use caution for more extensive areas of broken skin or areas affected by rashes not due to fungus. The oil may burn if it gets into the eyes, nose, mouth, or other tender areas. Some people have allergic reactions, including rashes and itching, when applying tea tree oil.<sup>10</sup> For this reason, only a small amount should be applied when first using it. Tea tree oil should never be swallowed, as it may cause nerve damage and other problems.

#### Historical or traditional use (may or may not be supported by scientific studies)

Other than its use as a spice, thyme has a long history of use in Europe for the treatment of dry, spasmodic **coughs** (page 139) as well as **bronchitis** (page 80).<sup>1</sup> Its antispasmodic actions have made it a common traditional recommendation for whooping cough. Thyme has also been used to ease an irritated gastrointestinal tract. The oil has been used to treat topical fungal infections and is also used in toothpastes to prevent **gingivitis** (page 203).

#### Active constituents

Many constituents in thyme team up to provide its antitussive (preventing and treating a cough), antispasmodic, and expectorant (thinning the mucus to allow for coughing out) actions. The primary constituents are the volatile oils, which include the phenols, thymol and carvacol.<sup>2</sup> These are complemented by the actions of **flavonoids** (page 516). Thyme, either alone or in combination with herbs such as **sundew** (page 749), continues to be one of the most commonly recommended herbs in Europe for the treatment of dry, spasmodic coughs as well as whooping cough.<sup>3</sup> Due to the low toxicity of the herb, it has become a favorite for treating coughs in small children.

## THYME

**Botanical name:** *Thymus vulgaris*

#### Parts used and where grown

This fragrant plant is indigenous to the Mediterranean region of Europe and is extensively cultivated in the United States. The dried or partially dried leaves and flowering tops are used medicinally.

**Thyme has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Bronchitis</b> (page 80) <b>Chronic candidiasis</b> (page 109) <b>Cough</b> (page 139) <b>Halitosis</b> (page 209) (oil of thyme rinse) <b>Indigestion</b> (page 260) <b>Infection</b> (page 265) Whooping cough

#### How much is usually taken?

The German Commission E monograph recommends a cup (250 ml) of tea made from  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–2 grams) of the herb taken several times daily as needed for a **cough** (page 139).<sup>4</sup> A fluid extract,  $\frac{1}{4}$ – $\frac{3}{4}$  teaspoon (1–4 ml) three times per day, can also be used. Another alternative is to use a tincture,  $\frac{1}{2}$ –1 teaspoon (2–6 ml) three times per day.

#### Are there any side effects or interactions?

Used as indicated above, thyme herbal preparations are generally safe. However, a spasmodic cough, particularly in a young child, may be dangerous and a health-care professional should be consulted before deciding on the proper course of treatment. The use of thyme by **pregnant** (page 363) or breast-feeding women is considered to be safe. Thyme oil should be reserved for topical use, as internally it may lead to dizziness, vomiting, and breathing difficulties.<sup>5</sup> Some people may be sensitive to use of thyme oil topically on the skin or as a mouth rinse.

# TURMERIC

**Botanical name:** *Curcuma longa*

## Parts used and where grown

The vast majority of turmeric comes from India. Turmeric is one of the key ingredients in many curries, giving them color and flavor. The root and rhizome (underground stem) are used medicinally.

**Turmeric has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Indigestion</b> (page 260) <b>Rheumatoid arthritis</b> (page 387)
★★★	Anterior uveitis (chronic) <b>Atherosclerosis</b> (page 38) <b>Bursitis</b> (page 87) <b>Genital herpes</b> (page 200) (topical) <b>HIV support</b> (page 239) Inflammation <b>Low back pain</b> (page 293) <b>Osteoarthritis</b> (page 38) (in combination with <b>boswellia</b> [page 644], <b>ashwagandha</b> [page 629], and <b>zinc</b> [page 614]) <b>Pre- and post-surgery health</b> (page 357)

## Historical or traditional use (may or may not be supported by scientific studies)

In Ayurvedic medicine, turmeric was prescribed for treatment of many conditions, including poor vision, rheumatic pains, and **coughs** (page 139), and to increase milk production. Native peoples of the Pacific sprinkled the dust on their shoulders during ceremonial dances and used it for numerous medical problems ranging from **constipation** (page 137) to skin diseases. Turmeric was used for numerous intestinal infections and ailments in Southeast Asia.

## Active constituents

The active constituent is known as curcumin. It has been shown to have a wide range of therapeutic actions. First, it protects against free radical damage because it is a strong **antioxidant** (page 467).<sup>1, 2</sup> Second, it reduces inflammation by lowering histamine levels

and possibly by increasing production of natural cortisone by the adrenal glands.<sup>3</sup> Third, it protects the liver from a number of toxic compounds.<sup>4</sup> Fourth, it has been shown to reduce platelets from clumping together, which in turn improves circulation and may help protect against **atherosclerosis** (page 38).<sup>5</sup> There are also test-tube and animal studies showing a **cancer** (page 87)-preventing action of curcumin. In one of these studies, curcumin effectively inhibited metastasis (uncontrolled spread) of melanoma (skin cancer) cells.<sup>6</sup> This may be due to its antioxidant activity in the body. Curcumin inhibits **HIV** (page 239) in test tubes, though human trials are needed to determine if it has any usefulness for treating humans with this condition.<sup>7</sup>

A preliminary trial in people with **rheumatoid arthritis** (page 387) found curcumin to be somewhat useful for reducing inflammation and symptoms such as pain and stiffness.<sup>8</sup> A separate double-blind trial found that curcumin was superior to placebo or phenylbutazone (an NSAID) for alleviating post-surgical inflammation.<sup>9</sup>

While a double-blind trial has found turmeric helpful for people with **indigestion** (page 260),<sup>10</sup> results in people with stomach or intestinal **ulcers** (page 349) have not shown it to be superior to a placebo and have demonstrated it to be less effective than antacids.<sup>11, 12</sup>

Preliminary research indicates a possible benefit of oral curcumin supplementation (375 mg of turmeric extract with 95% curcuminooids three times daily for 12 weeks) for chronic anterior uveitis (inflammation of the iris and middle coat of the eyeball).<sup>13</sup>

## How much is usually taken?

Turmeric extracts standardized at 90 to 95% curcumin can be taken in the amount of 250 to 500 mg three times per day.<sup>14</sup> Tincture, 0.5–1.5 ml three times per day, is sometimes recommended.

## Are there any side effects or interactions?

Used in the recommended amounts, turmeric is generally safe. It has been used in large quantities as a condiment with no adverse reactions. Some herbal books recommend not taking high amounts of turmeric during **pregnancy** (page 363) as it may cause uterine contractions and people with **gallstones** (page 193) or obstruction of bile passages should consult their healthcare practitioner before using turmeric.<sup>15, 16</sup>

## TYLOPHORA

**Common name:** Indian ipecac

**Botanical names:** *Tylophora indica*, *Tylophora asthmatica*

### Parts used and where grown

Tylophora is a perennial climbing plant native to the plains, forests, and hills of southern and eastern India. The portions of the plant used medicinally are the leaves and root.<sup>1</sup>

**Tylophora has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Asthma</b> (page 32)
★★★	<b>Diarrhea</b> (page 163)
	<b>Hay fever</b> (page 211)

### Historical or traditional use (may or may not be supported by scientific studies)

This plant has been traditionally used as a folk remedy in certain regions of India for the treatment of bronchial **asthma** (page 32), **bronchitis** (page 80), rheumatism, and dermatitis. In the latter half of the 19th century, it was called Indian ipecacuanha, as the roots of the plant have often been employed as an effective substitute for ipecac. The use to induce vomiting led to tylophora's inclusion in the Bengal Pharmacopoeia of 1884.<sup>2</sup>

### Active constituents

The major constituent in tylophora is the alkaloid tylophorine. Laboratory research has shown this isolated plant extract exerts a strong anti-inflammatory action.<sup>3</sup> Test tube studies suggest that tylophorine is able to interfere with the action of mast cells, which are key components in the process of inflammation.<sup>4</sup> These actions seem to support tylophora's traditional use as an anti-asthmatic and antiallergic medication by Ayurvedic practitioners.

These historical and laboratory findings have been supported by several human clinical trials using differing preparations of tylophora, including the crude leaf, tincture, and capsule. One clinical trial with **asthma** (page 32) sufferers, found that tylophora leaf (150 mg of the leaf by weight) chewed and swallowed daily in

the early morning for six days led to moderate to complete relief of their asthma symptoms.<sup>5</sup> In a follow-up trial with asthma patients, an alcoholic extract of crude tylophora leaves in 1 gram of glucose had comparable effects to that of chewing the crude leaf.<sup>6</sup> Another trial found similar success in reducing asthma symptoms using a tylophora leaf powder (350 mg per day).<sup>7</sup> However, the tylophora was not as effective as a standard asthma drug combination. One double-blind trial failed to show any effect on asthma for tylophora.<sup>8</sup>

### How much is usually taken?

Tylophora leaf—200 to 400 mg of the dried leaf per day or 1 to 2 ml of tincture per day—can be used to treat **asthma** (page 32).<sup>9</sup>

### Are there any side effects or interactions?

Patients using tylophora may experience temporary nausea and vomiting, soreness of the mouth, and loss of taste for salt, particularly with the fresh leaf and tincture.<sup>10, 11, 12</sup> The herb's safety for use during **pregnancy** (page 363) and breast-feeding has not been established. People with asthma should be closely monitored by a qualified healthcare professional.

## USNEA

**Common name:** Old man's beard

**Botanical name:** *Usnea barbata*

### Parts used and where grown

Usnea, also known as old man's beard, is not a plant but a lichen—a symbiotic relationship between an alga and a fungus. The entire lichen is used medicinally. Usnea looks like long, fuzzy strings hanging from trees in the forests of North America and Europe, where it grows.

**Usnea has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Common cold/sore throat</b> (page 129)
	<b>Cough</b> (page 139)
	<b>Infection</b> (page 265)
	<b>Pap smear (abnormal)</b> (page 3)

### **Historical or traditional use (may or may not be supported by scientific studies)**

Due to its bitter taste, usnea stimulates digestion and was historically used by herbalists to treat **indigestion** (page 260). It was also reportedly used over 3,000 years ago in ancient Egypt, Greece, and China to treat unspecified infections.<sup>1</sup>

### **Active constituents**

Usnic acid gives usnea its bitter taste and also acts as an antibiotic in test tube studies.<sup>2</sup> Test tube studies have suggested an anti-cancer (page 87) activity for usnic acid. However, this action has not been sufficient to warrant further investigation in humans.<sup>3</sup> Usnea also contains mucilage, which may be helpful in easing irritating **coughs** (page 139). Again, this has not been studied in humans.

### **How much is usually taken?**

Usnea, 100 mg three times per day, can be taken in capsules.<sup>4</sup> Tincture, 3–4 ml three times per day, can also be used.

### **Are there any side effects or interactions?**

There are no known side effects of usnea. It is considered safe for use in children. The safety of usnea during **pregnancy** (page 363) and breast-feeding has not been established.

## **UVA URSI**

**Common name:** Bearberry

**Botanical name:** *Arctostaphylos uva-ursi*

### **Parts used and where grown**

The uva ursi plant is found in colder, northern climates. It has red flowers and red berries, which bears like to eat. The leaf is used medicinally.

**Uva ursi has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Urinary tract infection</b> (page 436)

### **Historical or traditional use (may or may not be supported by scientific studies)**

The leaves and berries were used by numerous indigenous people from northern latitudes. Combined with tobacco, Native Americans sometimes smoked uva ursi. It was also used as a beverage tea in some places in Russia. The berries were considered beneficial as a **weight-loss** (page 446) aid. It was found in wide use for **infections** (page 265) of all parts of the body because of its astringent, or “drying,” action.

### **Active constituents**

The glycoside arbutin is the main active constituent in uva ursi and comprises up to 10% of the plant by weight. Hydroquinone derived from arbutin and *methylarbutin* is a powerful anti-bacterial agent and is thought to be responsible for uva ursi’s ability to treat **urinary tract infections** (page 436). It is believed to be most effective as a urinary tract antiseptic agent if the urine is alkaline.<sup>1</sup> No human trials have been published confirming the effectiveness of uva ursi in people with urinary tract infections.

### **How much is usually taken?**

The German Commission E monograph suggests  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (3 grams) of uva ursi steeped in about 5 ounces (150 ml) of boiling water and drunk as an infusion three to four times daily.<sup>2</sup> For alcohol-based tinctures, 1 teaspoon (5 ml) three times per day can be used. Standardized extracts in capsules or tablets (containing 20% arbutin), 700–1,000 mg three times per day, can also be taken. Use of uva ursi should be limited to no more than 14 days. To ensure alkaline urine, about 1½ teaspoons (6–8 grams) of sodium bicarbonate (baking soda) mixed in a glass of water can be taken. Baking soda should also not be taken for more than 14 days. People with **high blood pressure** (page 246) should not take baking soda. Uva ursi should not be used to treat an **infection** (page 265) without first consulting a physician.

### **Are there any side effects or interactions?**

Due to the high tannin content in uva ursi, some people may experience cramping, nausea, or vomiting. It is also not recommended for long-term use. Uva ursi should not be taken by **pregnant** (page 363) or breast-feeding women and should be used in young children only with the guidance of a healthcare professional.

## VALERIAN

**Botanical name:** *Valeriana officinalis*

### Parts used and where grown

Although valerian grows wild all over Europe, most of the valerian used for medicinal extracts is cultivated. The root is used in herbal medicine preparations.

**Valerian has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Insomnia</b> (page 270)
★★☆	<b>Anxiety</b> (page 30) (in combination with <b>passion flower</b> )
★☆☆	<b>Pain</b> (page 338)

### Historical or traditional use (may or may not be supported by scientific studies)

The Greek physician Dioscorides reportedly recommended valerian for a host of medical issues, including digestive problems, nausea, liver problems, and even urinary tract disorders. Use of valerian for **insomnia** (page 270) and nervous conditions has been common for many centuries. By the 18th century, it was an accepted sedative and was also used for nervous disorders associated with a restless digestive tract.

### Active constituents

Valerian root contains many different constituents, including volatile oils that appear to contribute to the sedating properties of the herb. Central nervous system sedation is regulated by receptors in the brain known as GABA-A receptors. According to test tube studies, valerian may weakly bind to these receptors to exert a sedating action.<sup>1</sup> This might explain why valerian may help some people deal with stress more effectively.<sup>2</sup>

Double-blind trials have found that valerian is an effective treatment for people with mild to moderately severe insomnia.<sup>3, 4</sup> Generally, valerian makes sleep more restful as well as making the transition to sleep easier, but does not tend to increase total time slept, according to these studies. Two trials have also found that a combination with **lemon balm** (page 701) is effective in

improving quality of sleep and in treating **insomnia** (page 270).<sup>5, 6</sup>

### How much is usually taken?

For **insomnia** (page 270), some doctors suggest 300–500 mg of a concentrated valerian root herbal extract (standardized to at least 0.5% volatile oils) in capsules or tablets 30 to 60 minutes before bedtime.<sup>7</sup> Non-standardized dried root products, 1.5 to 2 grams 30 to 60 minutes before bedtime, may also be used. As an alcohol-based tincture, 5 ml can be taken before bedtime. Combination products with **lemon balm** (page 701), **hops** (page 690), **passion flower** (page 722), and scullcap can also be used.

### Are there any side effects or interactions?

Research suggests that valerian does not impair one's ability to drive or operate machinery.<sup>8</sup> There is one case reported of a man experiencing severe cardiac symptoms that may have been due to withdrawing from valerian. This man abruptly discontinued taking valerian, after having used 5–20 times the recommended amount "for many years."<sup>9</sup> However, when taken at recommended amounts, valerian supplementation does not lead to addiction or dependence. In the case of an 18-year old college student who tried to kill herself by ingesting approximately 20,000 mg of valerian root (approximately 40–50 times the recommended amount), the only symptoms reported were fatigue, abdominal pain, and a mild tremor of the hands and feet.<sup>10</sup> Valerian does not appear to impair reaction time, alertness, or concentration the morning after use.<sup>11</sup> There are no known reasons to avoid valerian during **pregnancy** (page 363) or breast-feeding.

## VERVAIN

**Botanical name:** *Verbena officinalis*

### Parts used and where grown

The most commonly used species is European vervain (*Verbena officinalis*), though blue vervain (*V. hastata*) and *V. macdougalii*, among others, are probably interchangeable. *V. officinalis* is native to Europe, Asia, and Africa and has spread to North America. Other medicinal species are native to North America. The leaf and flower are used in herbal medicine.

**Vervain has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Colic</b> (page 121) (in combination with <b>chamomile</b> [page 656], <b>licorice</b> [page 702], <b>fennel</b> [page 676], and <b>lemon balm</b> [page 701])
★★★	<b>Depression</b> (page 145) <b>Dysmenorrhea</b> (page 171) (painful menstruation) <b>Indigestion</b> (page 260) <b>Sinusitis</b> (page 407) (in combination with <b>gentian</b> [page 680] root, primrose flowers, sorrel herb, and elder flowers)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Due to its bitter taste, herbalists used vervain to improve digestion. Vervain was also used to treat people with **depression** (page 145) and spastic pains in the gastrointestinal tract, as a mild diaphoretic (to induce sweating and promote mild fevers), and for all manner of female reproductive system problems when associated with melancholy or anxiety.<sup>1</sup> Early 20th century Eclectic physicians (doctors who recommended herbal medicines) in the United States felt vervain might be helpful for mild **digestive problems** (page 260).<sup>2</sup> Vervain also has a reputation as a traditional remedy for stimulating production of breast milk.<sup>3</sup>

#### **Active constituents**

The active constituents of vervain have not been thoroughly demonstrated. Glycosides, such as verbenalin and aucubin, and a volatile oil may all contribute to its activity.<sup>4</sup> No human studies have documented the use of this herb for any condition.

#### **How much is usually taken?**

A tea of vervain leaves and flowers is prepared by adding 1–2 teaspoons (2–4 grams) to a pint (500 ml) of hot water which is left to steep, covered, for 10–15 minutes.<sup>5</sup> Three cups (750 ml) per day are typically recommended by doctors. The taste of the tea is fairly disagreeable, therefore, most people prefer a tincture. Tincture, 1–2 teaspoons (5–10 ml) three times per day, is also suggested.<sup>6</sup>

#### **Are there any side effects or interactions?**

No adverse effects of vervain have been reported. Vervain should be avoided during **pregnancy** (page 363).<sup>7</sup> Although, traditionally, its use was during the last two weeks of pregnancy to facilitate labor. Vervain should be used during pregnancy only under the guidance of a healthcare professional experienced in herbal medicine.

## VITEX

**Common names:** Chaste tree, monk's pepper

**Botanical name:** *Vitex agnus-castus*

#### **Parts used and where grown**

Vitex grows in Mediterranean countries and central Asia. The dried fruit, which has a pepper-like aroma and flavor, is used in herbal medicine preparations.

#### **Vitex has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Premenstrual syndrome</b> (page 368)
★★★	<b>Female infertility</b> (page 187) <b>Fibrocystic breast disease</b> (page 189)
★★★	<b>Acne</b> (page 6) (associated with menstrual cycle) <b>Amenorrhea</b> (page 22) <b>Dysmenorrhea</b> (page 171) <b>Endometriosis</b> (page 182) <b>Menorrhagia</b> (page 314) (heavy menstruation) <b>Pregnancy and postpartum support</b> (page 363)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Hippocrates, Dioscorides, and Theophrastus mention the use of vitex for a wide variety of conditions, including hemorrhage following childbirth and assisting with the “passing of afterbirth.” Decoctions of the fruit and plant were also used in sitz baths for diseases of the uterus. In addition, vitex was believed to suppress libido and inspire chastity, which explains one of its common names, chaste tree.

#### **Active constituents**

Vitex contains several different constituents, including flavonoids, iridoid glycosides, and terpenoids. The

whole fruit extract, rather than one of its individual constituents, appears to be necessary for the medicinal activity of vitex.<sup>1</sup> Vitex does not contain hormones. The benefits of vitex stem from its actions upon the pituitary gland—specifically on the production of a hormone called luteinizing hormone (LH). This indirectly increases **progesterone** (page 577) production and helps regulate the menstrual cycle. Vitex also keeps prolactin secretion in check.<sup>2, 3</sup> The ability to decrease mildly elevated prolactin levels may benefit some **infertile women** (page 187) as well as some women with breast tenderness associated with **premenstrual syndrome** (page 368) (PMS).

A controlled clinical trial found that women taking 20 mg per day of a concentrated vitex extract for three menstrual cycles had a significant reduction in symptoms of PMS, including irritability, mood swings, headache, and breast tenderness.<sup>4</sup> Another double-blind trial found that women taking vitex had slightly greater relief from symptoms of PMS, including breast tenderness, cramping, and headaches, than those taking **vitamin B<sub>6</sub>** (page 600).<sup>5</sup> These trials support the findings of preliminary vitex trials for women with PMS.<sup>6, 7</sup> Vitex (32.4 mg per day), in combination with some homeopathic remedies, has also been found in a double-blind trial to successfully treat breast tenderness (also called mastalgia).<sup>8</sup>

A review of other trials and case reports suggests there is at least preliminary support that vitex should be considered for women with irregular periods, infertility, and mildly elevated prolactin levels.<sup>9</sup> Double-blind trials have confirmed the effectiveness of vitex at lowering mildly elevated prolactin levels in women.<sup>10</sup> According to one small trial, **acne** (page 6) associated with PMS, may also be reduced using vitex.<sup>11</sup>

#### How much is usually taken?

The German Commission E monograph recommends a daily intake—30–40 mg of the dried herb—in capsules or in liquid preparations.<sup>12</sup> Vitex is typically taken once in the morning with liquid for several months consecutively.

With its emphasis on long-term balancing of a woman's hormonal system, vitex is not a fast-acting herb and is unlikely to give immediate relief to the discomfort associated with PMS. For **premenstrual syndrome** (page 368), frequent or heavy periods, vitex can be used continuously for four to six months. **Infertile women** (page 187) with **amenorrhea** (page 22) (lack of menstruation) can remain on vitex for 12 to 18 months, unless **pregnancy** (page 363) occurs during treatment.

#### Are there any side effects or interactions?

Side effects may include minor stomach upset and a mild skin rash with itching. Vitex is not recommended for use during **pregnancy** (page 363) and should not be used concurrently with hormone therapy (e.g., estrogen, **progesterone** [page 577]).

## WILD CHERRY

**Botanical name:** *Prunus serotina*

#### Parts used and where grown

Although native to North America, wild cherry trees now grow in many other countries. The bark of the wild cherry tree is used for medicinal preparations.

**Wild cherry has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Chronic obstructive pulmonary disease</b> (page 114) (COPD) <b>Cough</b> (page 139)

#### Historical or traditional use (may or may not be supported by scientific studies)

Wild cherry syrup has been used traditionally by herbalists to treat **coughs** (page 139) and other lung problems. It has also been used to treat **diarrhea** (page 163) and to relieve pain.<sup>1</sup>

#### Active constituents

Wild cherry bark contains cyanogenic glycosides, particularly prunasin. These glycosides, once broken apart in the body, act to relieve coughs by quelling spasms in the smooth muscles lining bronchioles.<sup>2</sup> Although wild cherry is a commonly used ingredient in cough syrups, there are no published clinical trials in humans to support its use for this indication.

#### How much is usually taken?

Wild cherry tincture or syrup, 2–4 ml three to four times per day, is sometimes recommended for coughs.<sup>3</sup>

#### Are there any side effects or interactions?

Very large amounts (several times the recommended amount above) of wild cherry pose the theoretical risk

of causing cyanide poisoning, due to hydrocyanic acid.<sup>4</sup> However, this has not been reported in clinical practice. The safety of wild cherry during **pregnancy** (page 363) has also not been established.

## WILD INDIGO

**Botanical name:** *Baptisia tinctoria*

### Parts used and where grown

The plant is native to the midwestern United States and continues to grow primarily in this region. The root of wild indigo is used medicinally.

**Wild indigo has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Common cold/sore throat</b> (page 129) <b>Infection</b> (page 265) <b>Influenza</b> (page 269)

### Historical or traditional use (may or may not be supported by scientific studies)

Historically, the root of wild indigo was used to make blue dye. It was also used by European herbalists to treat **ulcers** (page 349) and several types of infections, including those affecting the mouth and gums, lymph nodes, and throat.<sup>1</sup>

### Active constituents

According to test tube experiments, the polysaccharides and proteins in wild indigo are believed to stimulate the **immune system** (page 255).<sup>2</sup> This might account for its role against the **common cold** (page 129) and **flu** (page 269). Wild indigo is rarely used alone and is a part of a popular European product for colds and flu that combines the herb with **echinacea** (page 669) and **thuja**.<sup>3</sup> The root also contains alkaloids, which may contribute to its medicinal actions.

### How much is usually taken?

Wild indigo is generally used in combination with herbs such as **echinacea** (page 669) and **thuja**. A tincture, 1–2 ml three times per day, is sometimes used. When taking the whole herb, 500–1,000 mg is taken as a tea three times daily.<sup>4</sup>

### Are there any side effects or interactions?

Higher intakes (over 30 grams per day) of wild indigo can cause nausea and vomiting.<sup>5</sup> Long-term use (more than two to three weeks) is not recommended. The safety of wild indigo during **pregnancy** (page 363) and breast-feeding has only been established in a product combining it with echinacea and **thuja**. Used according to the manufacturer's recommendations, the combination delivers 90 mg of wild indigo per day.

## WILD YAM

**Botanical name:** *Dioscorea villosa*

### Parts used and where grown

Wild yam plants are found across the midwestern and eastern United States, Latin America (especially Mexico), and Asia. Several different species exist. All of which possess similar constituents and properties. The root is used medicinally.

**Wild yam has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>High cholesterol</b> (page 223) <b>Menopause</b> (page 311)

### Historical or traditional use (may or may not be supported by scientific studies)

Wild yam has been used by herbalists as an expectorant for people with **coughs** (page 139). It was also used for **gastrointestinal upset** (page 195), nerve pain, and **morning sickness** (page 320).<sup>1</sup> Eventually, it was discovered that the saponins from wild yam could be converted industrially into cortisone, estrogens, and **progesterone** (page 577)-like compounds. Wild yam and other plants with similar constituents continue to be a source for these drugs.

### Active constituents

The steroidal saponins (such as diosgenin) account for some of the activity of wild yam. Another compound, dioscoretine, has been shown in animal studies to lower blood sugar levels.<sup>2</sup> An extract of wild yam was also found in a clinical trial to have **antioxidant** (page 467) properties and raised HDL, the “good,” **cholesterol** (page 223) in elderly adults.<sup>3</sup>

Contrary to popular claims, wild yam roots do not contain and are not converted into **progesterone** (page 577) or dehydroepiandrosterone (**DHEA** [page 503]) in the body.<sup>4, 5</sup> Pharmaceutical progesterone is made from wild yam using a chemical conversion process. This can lead to confusion—while wild yam can be a source of progesterone, it cannot be used without this pharmaceutical conversion, which cannot be duplicated by the body. Women who require progesterone should consult with their physician and not rely on wild yam supplements.

#### **How much is usually taken?**

Up to 2–3 ml of wild yam tincture can be taken three to four times per day. Alternatively, 1 gram of dried, powdered root can be taken three times each day.<sup>6</sup>

#### **Are there any side effects or interactions?**

Some people may experience nausea or vomiting when taking large amounts of wild yam (several times the amounts listed above). The safety of wild yam during **pregnancy** (page 363) and breast feeding has not been established.

## **WILLOW**

**Common name:** Willow bark

**Botanical name:** *Salix alba*

#### **Parts used and where grown**

The willow tree grows primarily in central and southern Europe, although it is also found in North America. The bark is used to make herbal extracts.

**Willow has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	<b>Low back pain</b> (page 293) <b>Osteoarthritis</b> (page 328)
★★☆	<b>Bursitis</b> (page 87) Fever <b>Pain</b> (page 338) <b>Rheumatoid arthritis</b> (page 387)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Willow bark was used traditionally by herbalists for fever, headache, **pain** (page 338), and rheumatic complaints.<sup>1</sup> In the late 19th century, the constituent sali-

cyclic acid was isolated from willow bark and went on to become the model for the development of aspirin (acetylsalicylic acid).<sup>2</sup>

#### **Active constituents**

The glycoside salicin, from which the body can split off salicylic acid, is thought to be the source of the anti-inflammatory and pain-relieving actions of willow.<sup>3</sup> The analgesic actions of willow are typically slow to develop but may last longer than the effects of standard aspirin products. One trial has found that a combination herbal product including 100 mg willow bark taken for two months improved functioning via pain relief in people with **osteoarthritis** (page 328).<sup>4</sup> Another trial found that 1360 mg of willow bark extract per day (delivering 240 mg of salicin) for two weeks was somewhat effective in treating pain associated with knee and/or hip osteoarthritis.<sup>5</sup> Use of high amounts of willow bark extract may also help people with low back pain. One four-week trial found 240 mg of salicin from a willow extract was effective in reducing exacerbations of low back pain.<sup>6</sup>

#### **How much is usually taken?**

Willow extracts standardized for salicin content are available. The commonly recommended intake of salicin has been 60–120 mg per day.<sup>7</sup> However, newer studies suggest a higher salicin intake of 240 mg per day may be more effective for treating pain.<sup>8</sup> A willow tea can be prepared from  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–2 grams) of bark boiled in about 7 ounces (200 ml) of water for ten minutes. Five or more cups (1250 ml) of this tea can be drunk per day. Tincture, 1– $1\frac{1}{2}$  teaspoons (5–8 ml) three times per day, is also occasionally used.

#### **Are there any side effects or interactions?**

As with aspirin, some people may experience stomach upset from taking willow. Although such symptoms are less likely from willow than from aspirin, people with **ulcers** (page 349) and **gastritis** (page 195) should, nevertheless, avoid this herb.<sup>9</sup> Again, as with aspirin, willow should not be used to treat fevers in children since it may cause Reye's syndrome.

## **WITCH HAZEL**

**Botanical name:** *Hamamelis virginiana*

#### **Parts used and where grown**

Although native to North America, witch hazel now also grows in Europe. The leaves and bark of the tree are used in herbal medicine.

**Witch hazel has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Cold sores</b> (page 119) (topical) <b>Eczema</b> (page 177) (topical) <b>Hemorrhoids</b> (page 219) (topical)
★☆☆	<b>Canker sores</b> (page 90) <b>Crohn's disease</b> (page 141) <b>Menorrhagia</b> (page 314) <b>Skin ulcers</b> (page 409) (topical) <b>Varicose veins</b> (page 440) <b>Wound healing</b> (page 319) (topical)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Native Americans used poultices of witch hazel leaves and bark to treat **hemorrhoids** (page 219), **wounds** (page 319), painful tumors, insect bites, and skin ulcers.<sup>1</sup>

#### **Active constituents**

Tannins and volatile oils are the main active constituents in witch hazel. These constituents contribute to the strong astringent effect of witch hazel. Pharmaceutical studies have suggested that witch hazel strengthens veins and is anti-inflammatory.<sup>2, 3</sup> Topical creams are currently used in Europe to treat inflammatory skin conditions, such as **eczema** (page 177). One double-blind trial found that a topical witch hazel ointment (applied four times per day) was as effective as the topical anti-inflammatory drug bufexamac for people with eczema.<sup>4</sup> However, another trial found that witch hazel was no better than a placebo when compared to hydrocortisone for people with eczema.<sup>5</sup> Witch hazel is approved in Germany for relief of local mouth inflammations such as **canker sores** (page 90).

#### **How much is usually taken?**

A tea of witch hazel can be made by steeping 2–3 grams of the leaves or bark in 150 ml of boiled water for 10 to 15 minutes.<sup>6</sup> The tea can be drunk two to three times daily between meals. A tincture, 2–4 ml three times per day, is also occasionally used.

In combination with warm, moist compresses, witch hazel extracts can be applied liberally at least twice each day (in the morning and at bedtime) on **hemorrhoids** (page 219). For other skin problems, ointment or cream can be applied three or four times a day, or as needed.<sup>7</sup>

#### **Are there any side effects or interactions?**

With internal use, witch hazel may cause stomach irritation and cramping.<sup>8</sup> In particular, it should not be taken internally in combination with medications, supplements or herbs containing alkaloids, as the tannins in witch hazel may interfere with absorption.

There are no known restrictions to the internal use of witch hazel during **pregnancy** (page 363) or breast-feeding.<sup>9</sup>

## **WOOD BETONY**

**Common name:** Betony, lousewort

**Botanical name:** *Stachys officinalis*

#### **Parts used and where grown**

Native to Europe, wood betony is now planted in many parts of the world with temperate climates. The primary portions of the plant that are used as medicine are the leaves and flowers, though historically the root has also been used. There are many similar species originating from Eurasia, including *Stachys sieboldii* (Chinese artichoke, kan lu) and *S. atherocalyx* (hedge nettle).

#### **Wood betony has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Anxiety</b> (page 30) <b>Gastritis</b> (page 195) <b>Shingles</b> (page 401) <b>Sinusitis</b> (page 407) <b>Stress</b> (page 415)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Wood betony was used in European folk herbalism as a remedy for respiratory tract inflammation, **heartburn** (page 260), urinary tract inflammation, **varicose veins** (page 440), **intestinal worm infestations** (page 343), and failure to thrive.<sup>1</sup> It was considered a calming remedy and was used for headaches as well as some forms of neuralgia, including **shingles** (page 401).<sup>2</sup>

#### **Active constituents**

The active constituents of wood betony have not been clearly identified. The tannins, alkaloids, glycosides, and volatile oil found in this plant and its cousins may

all contribute to its activity. Almost no research has been conducted on wood betony. Some Russian research in humans apparently suggests it may promote lactation, though the details of these studies are not readily available.<sup>3,4</sup>

#### **How much is usually taken?**

A tea of wood betony can be made by steeping 1 to 2 tsp dried leaf and flower in a cup of water for 15 minutes. One or two cups of this tea can be drunk per day.<sup>5</sup> Though generally better between meals, it can be taken with food for convenience or if there is any gastrointestinal upset.

#### **Are there any side effects or interactions?**

There are no known adverse effects from use of wood betony other than occasional mild gastrointestinal upset. Its safety in **pregnancy** (page 363) and breast-feeding is generally unknown, though as noted above it has been studied in Russia as a way to increase lactation.

## **WORMWOOD**

**Botanical name:** *Artemisia absinthium*

#### **Parts used and where grown**

The wormwood shrub grows wild in Europe, North Africa, and western Asia. It is now cultivated in North America as well. The leaves and flowers, and the oil obtained from them, are all used in herbal medicine.

**Wormwood has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★☆	<b>Irritable bowel syndrome</b> (page 280) (in combination with <b>ginger</b> [page 680], <b>bupleurum</b> [page 647], <b>schisandra</b> [page 744], <b>dan shen</b> , and other extracts)
★☆☆	Gallbladder inflammation <b>Indigestion</b> (page 260) <b>Parasites</b> (page 343) Poor appetite

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Wormwood is perhaps best known because of the use of its oil to prepare certain alcoholic beverages, most notably vermouth and absinthe. Absinthe, popular in the

19th century in Europe, caused several cases of brain damage and even death and was banned in most places in the early 20th century.<sup>1</sup> Wormwood oil continues to be used as a flavoring agent for foods, although in much smaller amounts than were found in absinthe.

As a traditional medicine, wormwood was used by herbalists as a bitter to improve digestion, to fight worm infestations, and to stimulate menstruation.<sup>2</sup> It was also regarded as a useful remedy for liver and gall-bladder problems.

#### **Active constituents**

The aromatic oil of wormwood contains the toxins thujone and isothujone. Very little of this oil is present in ordinary wormwood teas or tinctures.<sup>3</sup> Also existent in the plant are strong bitter agents known as absinthin and anabsinthin. These stimulate digestive and gall-bladder function.<sup>4</sup> Modern herbal medicine rarely uses wormwood alone. It is typically combined with herbs such as **peppermint** (page 726) or **caraway** (page 651) to treat **heartburn** (page 260) and even **irritable bowel syndrome** (page 280). Clinical trials are lacking to support the use of wormwood for any indication, however.

#### **How much is usually taken?**

A wormwood tea can be made by adding  $\frac{1}{2}$  to 1 teaspoon (2.5 to 5 grams) of the herb to 1 cup (250 ml) of boiling water, then steeping for ten to fifteen minutes.<sup>5</sup> Many doctors recommend drinking three cups (750 ml) each day. Tincture, 10–20 drops in water, can be taken ten to fifteen minutes before each meal.<sup>6</sup> Either preparation should not be used consecutively for more than four weeks.<sup>7</sup>

#### **Are there any side effects or interactions?**

Longer-term use (over four weeks) or intake of amounts higher than those recommended can cause nausea, vomiting, **insomnia** (page 270), restlessness, vertigo, tremors, and seizures.<sup>8</sup> Thujone-containing oil or alcoholic beverages (absinthe) made with the oil is strictly inadvisable—the oil is addictive and may cause brain damage, seizures, and even death.<sup>9</sup> Short-term use (two to four weeks) of a wormwood tea or tincture has not resulted in any reports of significant side effects. One study found there were no side effects when using less than 1 ml tincture three times per day for as long as nine months to promote digestive function.<sup>10</sup> Nevertheless, consult with a healthcare professional knowledgeable in herbal medicine before taking wormwood. Wormwood is not recommended during **pregnancy** (page 363) and breast-feeding.<sup>11</sup>

## YARROW

**Botanical name:** *Achillea millefolium*

### Parts used and where grown

This prolific plant grows in Europe, North America, and Asia. A number of species are used as garden ornamentals. The flowering tops of yarrow are used in herbal medicine.

**Yarrow has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Amenorrhea</b> (page 22) <b>Colic</b> (page 121) <b>Common cold/sore throat</b> (page 129) <b>Crohn's disease</b> (page 141) <b>Indigestion and heartburn</b> (page 260) Inflammation <b>Pap smear (abnormal)</b> (page 3) <b>Premenstrual syndrome</b> (page 368) <b>Ulcerative colitis</b> (page 433)

### Historical or traditional use (may or may not be supported by scientific studies)

Traditional herbal medicine has used yarrow in three broad categories.<sup>1</sup> First, it was used to help stop minor bleeding and to treat **wounds** (page 319). Second, it was used to treat inflammation in a number of conditions, especially in the intestinal and female reproductive tracts. Third, it was utilized as a mild sedative. Some or all of these historical uses occurred in Europe, China, and India. The ancient Chinese fortune-telling system known as the I Ching first used dried yarrow stems, then later replaced them with coins.<sup>2</sup>

### Active constituents

A number of chemicals may contribute to yarrow's actions. The volatile oil, which is rich in sesquiterpene lactones, and alkamides has been found to have anti-inflammatory properties in test tube studies.<sup>3,4</sup> Animal studies have shown this herb can reduce smooth muscle spasms, which might further explain its usefulness in gastrointestinal conditions.<sup>5</sup> The alkaloid obtained from yarrow, known as achilletin, reportedly stops bleeding in animals.<sup>6</sup> No human clinical studies have confirmed the traditional uses of yarrow.

### How much is usually taken?

The German Commission E monograph suggests approximately 1 teaspoon (4.5 grams) of yarrow daily or 3 teaspoons (15 ml) of the fresh pressed juice.<sup>7</sup> A tea can be prepared by steeping 1–2 teaspoons (5–10 grams) of yarrow in 1 cup (250 ml) boiling water for ten to fifteen minutes. Three cups (750 ml) a day can be taken. A tincture,  $\frac{1}{2}$ – $\frac{3}{4}$  teaspoon (3–4 ml) three times per day, can be taken. The tea, or cloths dipped in the tea, can be used topically as needed for minor skin injuries.

### Are there any side effects or interactions?

People who take yarrow may occasionally develop an allergy or rash.<sup>8</sup> Yarrow might increase sensitivity to sunlight. Yarrow should not be used to treat large, deep, or infected **wounds** (page 319), all of which require medical attention. Yarrow is not recommended during **pregnancy** (page 363) or breast-feeding.<sup>9</sup>

## YELLOW DOCK

**Botanical name:** *Rumex crispus*

### Parts used and where grown

Yellow dock is found in many places throughout North America. The root of the plant is used in herbal medicine.

**Yellow dock has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★☆☆	<b>Poor digestion</b> (page 260) Skin conditions

### Historical or traditional use (may or may not be supported by scientific studies)

Yellow dock has a long history of use as an alterative. Alterative herbs have nonspecific effects on the gastrointestinal tract and the liver. As a result, they are thought to treat skin conditions attributed to toxic metabolites from **poor digestion** (page 260) and poor liver function.

### Active constituents

Yellow dock contains relatively small amounts of anthraquinone glycosides, which may contribute to its

mild laxative effect.<sup>1</sup> It is also thought to stimulate bile production. It is often used as a digestive bitter for people with poor digestion. No human studies have been done on its use as medicine.

#### **How much is usually taken?**

A tincture of yellow dock,  $\frac{1}{4}$ – $\frac{1}{2}$  teaspoon (1–2 ml) three times per day, can be used.<sup>2</sup> Alternatively, a tea can be made by boiling 1–2 teaspoons (5–10 grams) of root in 2 cups (500 ml) of water for ten minutes. Three cups (750 ml) may be drunk each day.

#### **Are there any side effects or interactions?**

Aside from mild **diarrhea** (page 163) or loose stools in some people, yellow dock is rarely associated with side effects.<sup>3</sup>

## YOHIMBE

**Botanical name:** *Pausinystalia yohimbe*

#### **Parts used and where grown**

Yohimbe is a tall evergreen forest tree native to southwestern Nigeria, Cameroon, Gabon, and the Congo. The bark of this African tree is used medicinally. There are concerns, however, that the tree may be endangered due to over-harvesting for use as medicine.

**Yohimbe has been used in connection with the following conditions** (refer to the individual health concern for complete information):

Rating	Health Concerns
★★★	Erectile dysfunction (page 185)
★★☆	Weight loss (page 446)
★☆☆	Depression (page 145)

#### **Historical or traditional use (may or may not be supported by scientific studies)**

Historically, yohimbe bark was used in western Africa for fevers, leprosy, and **coughs** (page 139).<sup>1</sup> It has also been used to dilate pupils, for **heart disease** (page 98), and as a local anesthetic. It has a more recent history of use as an aphrodisiac and a hallucinogen.

#### **Active constituents**

The alkaloid known as yohimbine is the primary active constituent in yohimbe, although similar alkaloids may

also play a role. Yohimbine blocks alpha-2 adrenergic receptors, part of the sympathetic nervous system.<sup>2</sup> It also dilates blood vessels. Yohimbine inhibits monoamine oxidase (MAO) and therefore may theoretically be of benefit in depressive disorders. However, it does not have the clinical research of other herbs used for **depression** (page 145), such as **St. John's wort** (page 747).

Yohimbine has been shown in double-blind trials to help treat men with **erectile dysfunction** (page 185).<sup>3, 4</sup> Although, negative studies have also been reported.<sup>5, 6</sup>

#### **How much is usually taken?**

Standardized yohimbe products are available. A safe daily amount of yohimbine from any product is 15–30 mg.<sup>7</sup> Yohimbine should be used under the supervision of a physician. Traditionally, a tincture of the bark, 5–10 drops three times per day, has been used.

#### **Are there any side effects or interactions?**

Patients with kidney disease, **peptic ulcer** (page 349) or **pregnant** (page 363) or breast-feeding women should not use yohimbe.<sup>8</sup> Standard amounts may occasionally cause dizziness, nausea, **insomnia** (page 270), **anxiety** (page 30), increased **blood pressure** (page 246), and rapid heart beat,<sup>9</sup> though all of these are rare.<sup>10</sup> Using more than 40 mg of yohimbine per day can cause dangerous side effects, including loss of muscle function, chills, and vertigo. Some people will also experience hallucinations when taking higher amounts of yohimbine.<sup>11</sup> Taking 200 mg yohimbine in one case led to only a brief episode of hypertension, palpitations, and anxiety.<sup>12</sup> People with post-traumatic stress disorder<sup>13</sup> and panic disorder<sup>14</sup> should avoid yohimbe as it may worsen their condition.

Foods with high amounts of tyramine (such as cheese, red wine, and liver) should not be eaten while a person is taking yohimbe, as they may theoretically cause severe high blood pressure and other problems. Similarly, yohimbe should only be combined with other antidepressant drugs under the supervision of a physician, though at least one study suggests it may benefit those who are not responding to serotonin reuptake inhibitors such as fluoxetine (Prozac).<sup>15</sup>

#### **Special United Kingdom considerations**

Yohimbe may be prescribed by a doctor or dispensed under the supervision of a pharmacist.

## About Healthnotes

Healthnotes, Inc. (HNI) is the premier provider of reliable, easy-to-use health, food, and lifestyle information for Web sites and interactive touch-screen kiosks. Used by leading supermarkets, pharmacies, and health food stores in the United States, Canada, and the United Kingdom, Healthnotes Retail Solutions empower consumers to make educated decisions and drive product sales—online and in-store. HNI also generates Web applications that are licensed to e-commerce and health-related Internet sites worldwide. On the Web: [www.healthnotes.com](http://www.healthnotes.com).

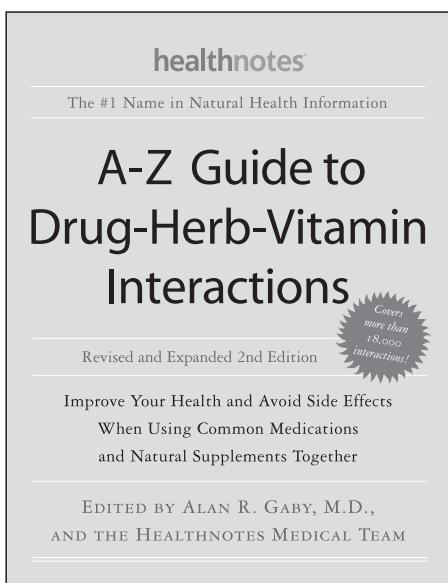

Overseen by Chief Medical Editor Alan R. Gaby, M.D., the Healthnotes interdisciplinary writing team includes experts from the fields of medicine, pharmacy, nursing, naturopathy, public health, and chiropractic. We regularly update our knowledge base, annually reviewing thousands of articles published in more than 600 peer-reviewed medical journals to ensure that consumers receive fully referenced, up-to-date health information based on the latest scientific and medical research.

### **Alan R. Gaby, M.D., Chief Medical Editor**

An expert in nutritional therapies, Chief Medical Editor Alan R. Gaby is a former professor at Bastyr University of Natural Health Sciences, where he served as the Endowed Professor of Nutrition. He is past president of the American Holistic Medical Association and gave expert testimony to the White House Commission on Complementary and Alternative Medicine on the cost-effectiveness of nutritional supplements. He has authored *Preventing and Reversing Osteoporosis* (Prima Lifestyles, 1995) and *B6: The Natural Healer* (Keats, 1987) and coauthored *The Patient's Book of Natural Healing* (Prima, 1999), *The Natural Pharmacy* (Three Rivers Press, 2006), and the *A-Z Guide to Drug-Herb-Vitamin Interactions* (Three Rivers Press, 2006). Dr. Gaby has conducted nutritional seminars for physicians and has collected more than 30,000 scientific papers related to the field of nutritional and natural medicine.

### A-Z Guide to Drug-Herb-Vitamin Interactions

0-307-33664-6

\$22.95 paper (Canada: \$32.95)

Written by a team of experts from the fields of medicine, pharmacy, naturopathy, and public health, the *A-Z Guide to Drug-Herb-Vitamin Interactions* covers the ways in which common prescription and over-the-counter drugs interact with herbs, vitamins, and foods, including potential nutrient depletions, interference with drug actions, reduction of drug side effects, and interference with drug absorption (bioavailability). Learn how some herbs and vitamins help drugs work better, discover why certain drugs and supplements should never be taken together, and find out which drug side effects can be reduced by taking the right vitamin or herb.

Healthnotes reliable health, food, and lifestyle information is available throughout the United States and United Kingdom. Ask your local pharmacy, supermarket, or health food store if they offer Healthnotes in-store or online.
